Hi Mark

I'll admit I have never actually noticed it but your experience sounds plausible.

So me thinking in fundamental terms.

- The ground strap not working implies a charge and discharge cycle in the wheel/axle.
- When you corner the tyre/road, tyre/wheel, wheel/axle conductivity (or insulation properties) changes.
- When the road surface changes physical or conductive properties also change.
- Wet weather mixes wth the road dirt and produces are better conductive path and thus less of a voltage to discharge.

Does applying the brakes (better conductivity hub/disc to axle/car) change or reduce the noise? (It will also distort the tyre shape in a like mannner to cornering so this test may be invalidated. Try just making the pads bind slightly with the drum/disc so it doesnt affect tyre shape)

Does driving on a noisy stretch with a wheel on the lane marking paint yield slightly less noise? (Wow, a new way to measure road speed!) If this gets to be a positive test you can try one side or the other to see if it is wheel dependent. (The kerb side tyres will of course have slightly more surface on the road due to road camber,)

Hard to test but does the noise stop straight away on wet pavement or does the water have to take some time to get well ingrained onto the tread and side surfaces of the tyre?

The more tyre surface that is on the road (eg smooth pavement, cornering G or wet pavement) the more likely the static charge will discharge at a lower voltage (ie less noisy) Can you make the problem worse by adding some more air to your tyres?

Road material conductivity to the underlying "ground" I dont think would be that significant but I'll admit I have never measured it. I would have thought that it is low enough resistance (including any rebar!) to not be factored in. I am prepared to be shot down over this though!

Interesting/Intriguing situation! You can of course just try some of that conductive powder that goes inside the tyre. Something like that green roadside puncture repair stuff may also help and additionally give you some protection for its priamry use!

Please get back to us with what you find.

Cheers Bob VK2YQA/W5 East Texas

(It is too dangerous for me to use AR in the car nowadays. I am so use to veering the "wrong way" from driving for so long on the other side I cant afford the risk! Sigh! - Yeah I also spell "tyre" the other way!)

4128. HF Diversity reception ?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-06 12:59:30 UTC
From: Henry Kolesnik <kolesnik@nojunksbcglobal.net>
Message-ID: <SSBQk.4258$W06.1779@flpi148.ffdc.sbc.com>
Source record: 20352

I know that Hallicrafters made a dual diversity set up and RCA used three AR-88s in a trioka, selecting the best signal with a tone decoder that switched in the best and let the other/s idle or squelched. I've heard that Collins used the R 390 (51J or 51S?) , and Hammarlund the Super Pros (only 600s or others?). It seems like three antennas spaced about 1000 feet apart on an equilateral triangle was a 100% solution. Did the Brits use it a Bletchley? But I don't see anything these days and have to wonder if diversity reception was made obsolete by SSB or the news & financial services using wire for TTY. I also know that Telstar was the final nail. Was the primary use for RTTY or was it used to voice well as CW? Anyone have some real personal experience to offer?
Thanks

Question: you say the static only occurs when the car is moving and
gave two scenarios where the car is moving: turning the corner from X
to Y (with static) and A to B (no static). My first question is are
these right turns, left turns or one of each? Is there a traffic light
at one and not at the other? Do you hear the static when driving
straight or performing the turns in other locations? Two theories
here: 1)is that maybe when you turn, something is coming into contact
with something else completing a circuit (or alternately seperating
and breaking a circuit) that would result in your static and 2) if
turn X to Y and A to B are at different intersections, there might be
something in the environment at the X to Y intersection that may not
be present at the A to B intersection - such as a traffic light and
its sensors and controllers, a business's sign etc...

My second question is have you tried the static producing maneuver
with the radio turned off? Just curious as to if the source of the
noise is from the sound system or maybe from another source that you
may not have noticed before you started listening to the AM radio -
car bodies and panels can flex some when under g loads like turns and
that could be the source of your noise.

I don't own one- but believe the Elecraft K3 can do diversity but woud
require the 2nd RX option.
There's space diversity (which you allude to) but also polarity diversity.

Space diversity is what they call it for microwave systems and they also
use frequency diversity. I've not heard of polarity diversity used on
commercial HF systems but I have used it quite a bit myself with a
horizontal dipole and a 18AVT. The military and FEMA use a computer
control systems to automagically establish links on various bands for a
round tables, and switching to the best link whenever required. I can't
recall the acronym but I hams have a PC based system. I've seen it in
use at a swapmeet using Sunair transceivers.
Does the Elecraft have a built in tone decoder?

Years ago at Collins we used a frequency diversity system that sent the same signal on upper and lower sideband. Additional improvement was achieved by delaying one sideband a few milliseconds, then doing the inverse delay at the receiving end. The time delay approach worked well, but never caught on commercially.

Additionally, separate antennas were deployed for space diversity. I have forgotten the siting guidelines.

The frequency diversity system was used for RTTY, and antenna space diversity for voice/data.

So get yourself a decent portable AM radio. Use it instead and if you
still hear the same static at the same locations, then you'll know

it's not the car.

My assumption is that it is the wiring in the car. Like a broken ground wire near the wheel well or even corroded wires.

You can also buy filters which are generally capacitors that can be installed before the radio.

I remember reading some time ago where some gal had this constant noise not in her car radio, but her teeth! She tracked the source down and found it to be a local radio station she was always passing.

Now me personally, I can never figure this one out.
Most of the time, when ever I go to bed, I'll hear a radio station. It's just enough to be annoying. I can rarely tell what's being said or played. I only hear it when I'm laying down on the bed, not sitting up. So I figure it has to do with the springs.

Henry Kolesnik. WD5JFR wrote:
"It seems that three antennas spaced about 1000 feet apart on an
equilateral triangle was a 100% solution."

Radio Free Europe relayed broadcasts from Munich to Lisbon by HF.
Satellites now make HF obsolete.

The point to point relay used one or more rhombics in Munich and three
in Lisbon for triple diversity reception. The three rhombics in Lisbon
may not have had optimum spacing. We had to clear cork and olive trees
to make room, but the recieved signals in them faded separately, in
spite of their side by side placements. We had apace diversity. All
rhombics were horizontal.

Frequency diversity was also used by transmitting on more than one
frequency in Munich. More than one horizontal rhombic was sometimes used
in Munich. Due to ionospheric polarization scrambling, no attempt was
made at polarization diversity.

Each receiving rhombic fed three or more receivers. The outputs of three
receivers were fed to an election box which selected the strongest and
least noisy signal while squelching all others in its group.

Henry mentioned, among others, the 51-J and SP-600 receivers. The 51-j
was incompatible with this mission. It had too many spurious responses.
We once tried to use one as a bridge detector at a transmitter site and
it was useless. The SP-600 has the front end selectivity required.

We used double sideband (AM) transmissions, but the SP-600`s had
selectable sideband responses which allowed us to supress interference
on one side of the carrier frequency.

These TDR systems worked like gangbusters.

Best regards, Richard Harrison, KB5WZI

"Wheel static only on some patches of pavement?"

Why any wheel static ever? Springs used to be installed in hubs to make a sliding contact between the axle and the wheel. They must still be available.

Graphite can be added to axle grease as is usual with speedometer cable lubrication. Graphite is powdered carbon and conductive.

Best regards, Richard Harrison, KB5WZI

I refute things you say quite often, but you ignore them.
As an example, you constantly state that an antenna should
be a full wave length in order to live a productive and useful life.
You claim such an antenna is in equilibrium. Whatever that is
supposed to mean to you. We don't know how equilibrium applies
in your case, as you refuse to tell anyone when questioned.
When I state that a full wave has no real efficiency advantage vs
a half wave, a statement which almost everyone knows is true,
you ignore it.
Of course, using a small antenna the size of two shoe boxes is
not really a full wave antenna. It's still a very small antenna fed
with a loading coil made up of a full wave length of wire, if I
understand what you are doing. And with your winding technique,
it's quite easy to see how this could be a very lossy method to
feed such a small radiator. You basically have a dummy load on
a stick.
A good 160m mobile antenna setup would tear it a new one.. :/

> So I will assume that the program is accepted for Yagi' but not for
> radiators in equilibrium.

How can a radiator be in equilibrium? You are talking about a
piece of metal.

> All this is not unusual a lot of things that were found out were
> delayed from the public because of people just couldn';t take change.

Change... Hummm.. A common Obama mantra..
Change can be good, or change can be bad.
Throwing a lot of the Wall Street CEO's in prison would be a
fairly good change.
A new president who thinks he can bend the constitution to suit
his personal agenda would not be a good change.
Ignoring proven data and replacing it with faulty unproven data would
not be a good change.
Using proven data and building on it to prove a new design or theory
would not be a bad change, if the new design or theory can pass
the scrutiny of rigorous testing over a period of time.

Using conjured up baffle gab to try to prove a new theory is
not going to cut it in the change dept.
BTW, I mention Obama quite a bit, and it's probably no secret I'm
no fan of his.
But I want to mention it is not on a personal level, or due to his
skin color, etc. I'm sure he can be a fairly decent guy at times,
but I still think he's a blatant socialist, and I have little use for
him.
He's a constitutional attorney who has no respect for the
constitution. IE: he'd like to take a big crap on the 2nd
amendment if he ever gets the chance for just one example.
This is not to say I really like McCain either..
I'm more of the independent Libertarian ilk.. If a politician can't
follow the constitution, I have zero use for them.

But back to the matter at hand..

> Those who do not understand the rules of science with respect to
> radiators say it is bafflegab because they don't understand the
> sciences.

I understand enough to tell a turd from a diamond any day.
An Einstein level of reasoning is not required for this simple
task.

> So I will let it go at that and assume that I am the one out of step.

You have taken the first step towards recovery.

> You and others have made your point and there is no such thing than a
> better antenna than the Yagi and that all is known is about antennas
> and nothing that is not printed in a book is acceptable to radio hams.
> I get the message and that should make every one happy

Just more whining from a disenchanted pseudo inventer..
I don't even know how the poor Yagi got involved. The yagi
has zero to do with anything I have argued about.
A contra wound dummy load on a stick, and a yagi and
about as different animals as chipmunks and baboons.

Or are you know abandoning the dummy load on a stick,
and returning to the perverted array with skewed elements
you harped on quite a few months ago?
You know, the one that provided less performance than
the properly designed yagi with an equal number of elements..
You know, the one I called the cluster%#&* antenna..
Chortle.. :/

Heh heh. Yeah, long time.
We made our own time delay box under Navy funding. In a prototype, we provided the time delay by recording the RTTY signal on tape and playing it back soon afterwards on a different tape head. The original and delayed were then sent on different sidebands. Noise was simulated with recorded static, and the noise audio was injected at the receiving end before deconstructing the delay with another tape deck.

IIRC, we found combinations that gave about a 3-5 db improvement. Fun project that would be even more fun with modern circuitry.

my icom 2820h does diversity, thou i really understand that in
a 'fm' uhf/vhf rig

I was sorta surprized that the flex radio has diversity, i mean
why not , but what i really wonder is if you had two nicely
spaced antennas aside from obvious a/b switching of the
antennas which you could do w/a coax switch i wonder how it would
or if it would be able to reduce noise both a) local and b) not
local

very interesting

as far as commercial, I work at a phone company we have a
cellular division and most all of our sites have very
complicated diversity systems built in , as most of the problems
we have are typically caused by multipath

on the same front data modems such as for example the (sierra)
airlink raven X evdo modem has a 2nd antenna port for rx
diversity ant the GSM models typically don't have it least not
that i ever saw

so diversity isn't dead but it's a best kept secreate sorta

Yes. It appears he has a dipole two shoe boxes long. The ARRL Antenna
Book has an interesting section on "Short Antennas" that starts on on
page 6-21 in my 20th edition. On page 6-30 it says:
"Loading is always a compromise; the best method is determined by the
amount of space available and the band(s) to be worked.
The simplest way to shorten a dipole is shown in Fig 53. If you do not
have sufficient length between supports, simply hang as much of the
center of the antenna as possible between the supports and let the ends
hang down.

Thanks for that information. Perhaps the American Tower parts is
made for the "New" Rohn, as the tower sections I am using are
brand new old stock I bought about 30 years ago and put in storage
for when I wanted to upgrade the towers. Ike took care of my
Rohn 25, so anyway, the problem is quality control at the American
Tower factory not the Rohn changes. Either their manufacturing jigs
are a joke, or the welder was hungover the day they fabricated this
hinged base, but I know they deliberately knew it was bad, as the
hinge bolts and securing bolts are 1/2" to take the load. They
shipped the thing with 3/8" bolts to allow slack in several
directions, and even that would not work. In order to get the hinge
to work, get this, you have to remove ALL 4 BOLTS. Try that with
a 60 foot tower bolted to the hinge.

Also, the hinge plate was warped, and the pins that go into the legs
of the Rohn ware off in two directions, the holes were axially
rotated so the bolts would not line up, and they would go too far into
the leg so the holes would not line up vertically. It's hard to
describe, but you would have to see this to believe it. I had to use
a automotive scissors jack and gobs of heavy silicone grease, and a
baseball bat and large heavy axe to just get the pins on the hinge to
go into the legs of the Rohn. Two of the legs holes could be made to
line up, the third one was impossible, off in two directions.

Then, the tower people tried to say it was ROHN's fault.... he he. I
sent them digital pictures and have not heard back from them, but
looks like I will have problems getting my money back.

The galvanize was very thick and thorough, heavy plates, it's just
they the parts don't fit together, no after assembly testing, no
quality control, although there was a big red sticker on the thing.
This one really slipped through the cracks. We will see if they stand
behind their products or not. My son just graduated from law school,
would be a good first case for him... he he...

The "Old" Rohn products were excellent, I assembled many a tower over
the years and never had any matching problems. Now I'm going to use
a HAZER with this, my last tower...

Jim

Dear JB;

Don't know if you are familiar with a hinged tower base, but the only way this one would "hinge" is to remove all 4 bolts. Try that with a 60 foot tower on the hinge. Yes, I tried everything with two sections and it was a total nightmare, impossible to work as advertised. I sent digital pictures to the factory, have not heard back a peep. I had to use a scissors jack, baseball bat and large axe just to get the hinge pins inside the tower legs, along with lots of heavy silicone grease, thent he holes would not line up...

Hello Mark,
I used to drive a semi trailer years back, and had the same problem. It occurred only in fine hot weather, and the static build up used to wipe out 80m mobiling, plus the Am receiver on the broadcast band. It was what I call "Tyre Static"

I noticed that in wet or damp weather it didn't occur, so I cured the problem by simply introducing some graphite powder into the grease of the outer wheel bearing on the front axle.

Later on I found that a molybdenum based greases did the same job, without the mess of handling the graphite powder.

I also found that steel belted radials were the culprit, but the early rayon biased tyres didn't suffer from the static build up problem at all. Main problem was that the rayon biased tyres didn't have the speed or load ratings the steel belted tyres have.

A big problem is that nowadays with the introduction of sealed wheel bearings and front wheel drive vehicles makes it nigh impossible to introduce graphite powder or to re-grease the wheel bearings.

By experimentation I found another cure, that was to put some graphite powder inside of the tyre before mounting the tyre on the rim (wheel), that reduces it as well. One can let the air out of the tyre and introduce graphite powder through the valve stem and then re-inflate the tyre.

I found that the graphite powder inside of the tyre did not affect the at all, we used to recap our truck tyres up to 3 times, only thing was the tyre fitters hated dealing with the graphite inside of the tyre.

On another problem not really related to highway use is that when farm tractors were fitted with UHF CB, ploughing in a paddock, static noise used to build up to a point where communication were impossible even over a short distance. The cure was to wipe the antenna down with a dry cloth.

Hope this helps
HarryH

I have 2 older CB BASE station radios. ONE IS SSB.. and the other is AM only

And I have a 100 + watt Knight T 175 AMP. 10 mtr and 6 mtr AMP. ALL THIS EQUIPMENT IS IN NEED OF REPAIR. THE AM unit comes on and I got sound out of it. Squelch Noise. COMES WITH NICE TURNER DESK MIC

THE SSB radio has NO power cord.. SO I could not power it. COMES with MIC.,.

THE AMP powered up.. Made some noise. SO I pulled the plug.

Pictures of all above by e-mail.

I will trade for a NON working HF transceiver.

I used to run HF mobile, and had this same problem all the time. I had
so many bonding straps under my truck that mechanics and oil change
personnel would ask what they were for. I operated mainly on 40 and 80,
and the engine/computer/fuel pump noise was very low. But, the tire

noise was a big problem. For some reason, bias ply tires produced the most noise, and radials the least. There was always a difference being on the road, and the shoulder. On dirt roads, no problem at all. I tried graphite in the tires, but never thought to try it in the axle grease.

A lot of time when you cross the state line the asphalt changes and
you can hear the difference. I noticed a big difference as soon as I
crossed into Ga from Fl the other day. Fl had the new asphalt that is
suppose to give you more traction in the rain and Ga hadnt upgraded
their's yet. I didnt realize the stactic was coming from the road/
tires until it turned off like someone threw a switch as soon as I
crossed the line.

Richard Clark wrote:
"An antenna is not in "equilibrium" so says Marx (of Hart, Shaffner & Marx)."

How about Chico, Harpo, and Groucho?

Art Unwin hopes to stump us by not defining what he means if anything by "equilibrium". A synonym, "balance" is often used in radio. Terman defines "balance" on page 901 of his 1955 opus:
"It is sometimes desirable to deliver power to a grounded antenna through a two-wire transmission line or, conversely, to use a coaxial cable line to deliver power to an ungrounded antenna system that is symmetrical with respect to ground. In either case, it is necessary to convert between a balanced system that is symmetrical with respect to ground, and an unbalanced system in which one side is grounded."

That seems to capture a problem we had here. Art is unbalanced and we are well grounded. None of us is in equilibrium.

"You`ve had your knickers in a twist ever since I proved your "loophole" antenna did not work as you (Art) claimed and its all gone downhill since then."

Yes. As I recall, Art claimed to have discovered something like the "gamma match" shown on page 26-9 of my 20th edition of the ARRL Antenna Book. Of course it`s been around nearly forever.

Art claimed radiation from the small gamma-loop strongly reinforced the dipole`s desired radiation. Art rejected the contention that radiation from the small loop is only directed in the plane of the loop so therefore only helps in the directions of the zenith and the earth and gives no help in the horizontal plane perpendicular to the dipole.and broadside to the small loop.

If Art patented the idea that the matching system radiated to significantly enhance the dipole`s desired radiation, he should not expect riches in royalties.

Best regards, Richard Harrison, KB5WZI

Yes I was granted a patent under " a constant impedance antenna
system"
and it is a matter of record despite what you have stated. And that is
all I wanted,.
a record of my work.

Proves my point about checking things out before trying to put it up.

You bought it on Ebay from OldTowerGuy? The name says "let the
buyer beware" In that case, at least you got a "tower". Did you check
how bad the rust was before putting it up?

We have all been burned at some time in our lives. I took a 327 Chevy
block to be rebuilt, and they put me off for over a year. After much
cajoling and even hitting them with a lawsuit just to get (some) of the
parts back, I dropped the suit and they (local mob I guess) sicked
the cops on me and I was followed around and pulled over constantly
and threatened all over town until I joined the service just to get away.
I figured that if I was going to be shot at, I might as well go to war and
get paid for it.

I guess the shop was a front for political contributions or something.

Ah! There we have chaotic harmony, not equilibrium. Perhaps more "attuned" to Gussian arrays. For haberdashery (what I presume Art describes here in this group), Hart, Shaffner & Marx is the zenith of equilibrium in dress (but not antennas).

>Art Unwin hopes to stump us by not defining what he means if anything by
>"equilibrium".

More the problem is that Art may have redefined the word "shoebox" which must be his metric standard for something the size of a WalMart store. If he had an antenna the size of two WalMart stores side-by-side, then yes, his claims would make sense.

So, in the vocabulary of Authur-speak:
Shoebox: One WalMart building.
Equilibrium: Matching fashions for men's levitation wear.
Paramagnetic: Skydiving at the North Pole.
Diamagnetic: Calorie cutting by eating only magenta colored food.
Array: Any jumble of rusted barbed wire sections.
Director: A reflector of an array.
Reflector: A director of an array.
Radiation: Bugs that hit your windshield (aka particels)
Resonance: Wiper action of flicking radiation off your windshield.
Antenna: A patent for a method of dividing by zero in checkbooks.

Art you are still under the delusion that if you get a patent it
means your idea is valid.
No, it just means it was your idea. At one time you had to give some
proof of the validity of the concept but this is no longer true. If
you want to get a patent on a Star Trek type "transporter" or "warp

drive" go ahead, you can probably get one. You can even patent something that already has a patent. The patent office will not keep you from screwing up.

I'm no metallurgist so forgive my ignorance. Most of
us have had the problem of interfacing copper to
aluminum. Is there some sort of alloy terminal block
that will accomplish that feat? Seems simple enough
to create an alloy that gradually transitions from
copper to aluminum but what do I know?

No Jimmie
I had to go to Washington to provide the proof in the 90"s and it was accepted
and that is all I cared about. I did not write articles for the radio magazines or anything like that
I do it purely to provide a record of my work
I just moved on to other things but at least it is available to hams to use or reject.
This is no different from what I am doing now with this new antenna, I applied for
a patent and then shared it with the ham community, is that so bad?
You can put the constant impedance antenna on EZNEC for yourself or ignore it
Many others on this group Richard included don't know how to operate computors let alone
work on antenna programs themselves so they are not talking from experience but from teachings reeived
over half a century ago after which they have stopped learning. If any of these had any savvy they would have put some of the things I have stated
and proved things one way or another but they don't want to as it means change. Now if you are "wired" like Richard then you are happy to join him
in the war of words as the othe Richard has and a few others. As for me I have shared all and you can take it or leave it, your choice. At the moment it is a queer road on this group where people want to attack those who have new ideas or challenges the status quo but as yet have only relied on insults
in the absence of individual thought or possibly suspend or get rid of patents and the like as they only promote change.
The group can get angry with me if they wish because of my work but there is no way they are going to stop me doing it for what ever reason they have in mind. Sooner or later somebody with some smarts and some get go will look at things for themselves and test thgem out on a computor which now apears to be accepted by all and then decide whether they want to build on them or not, they will not rely on the opinions of this group as there is nothing provided to study just venom. So Jimmie I congratulate you on all your patents obtained as it shows you are capable of original thought where others are lacking

Cecil, there are plenty of connectors (Bronze?) on the market that
accept copper/alluminum
combinations. On the other hand I understand that if the joint is free
from the atmosphere
i.e. a tight interface the problem is not all that bad, G.E proved in
court during the 50's that if the connection
is tight or embedded an increase in resistance does not occur, I
believe that analysis still stands.
Co defendants that could not provide a similar defence got hammered
because their joints did
not provide a virgin interface thus existing corrosion was trapped
thus it could grow.to a sizable resistance

Jim
The hinge on my fold over is corroded so I am about to build my own
"hazer"
I am using the square extruded aluminum that is available in the
stores and I have oibtained
some ball bearing pads that are used for inter conveyor use. Each of
the tubular tower sections
will be in contact only with these bearing pads so they are either
side of the tower tubular section which allows them
to by-pass connecting bolts with out hinderence. The addition of
combination ladder hooks provide a measure of safety.
The cost of such is way below anything that you can get commercialy
and the electric
winch is available on E bay for about $100. The structure of the above
is of a nut aand bolt type so welding availability is not a factor.
Have fun

If the road surface interface is not "keyed" to the moving part then
statitic will always
occur. If there is a contradiction in velocity of the two interfaced
parts static will occur,
if the two surfaces maintain the same velocity static will not occur.
Thus static production
depend purely on relative velocity which is governed by friction in
your case.

This should read "sooner or later Art will grow some smarts and will
look at things for himself, and test them out on a computer if he
feels
so compelled, and then decide if he wants to build one or not. "

At this late stage in the game, I would have thought you would
have made a decision by now. You know, like build the freakin
thing and test it out against radiators of known properties.
In some parts of civilization, this is called "falling asleep at the
wheel".
:/

>to create an alloy that gradually transitions from
>copper to aluminum but what do I know?

As I understand it, the problem with these connections results from at least two factors:

- Different galvanic potential. When these metals are in contact, and there's also an electrolyte present (e.g. moisture plus almost any sort of salt), one of the metals will take on the role of an anode, and will start corroding away.

- Different thermal coefficients of expansion... repeated heating and cooling puts mechanical stress on the junction of the two wires and can cause the joint to loosen, which increases the resistance, which increases heating when current flows through the joint, which increases thermal stress...

In order to use an alloy intermediary to reduce the problem, you'd need one which is midway between aluminum and copper in both galvanic potential, and thermal coefficient of expansion. I tend to doubt whether using a single, monolithic piece of alloy would eliminate the fundamental problem... it'd just spread it out into two separate junctions with lesser but still-nonzero mechanical and galvanic incompatibilities.

A tapered alloy as you suggest may well be possible but I suspect that it'd be expensive to make, and might have other problems. Aluminum can be alloyed with copper, but the resulting alloy might be just what you don't want for electrical junctions... the 2000 (or 2xx.x) aluminum/copper alloys are said to be extremely hard but prone to stress corrosion cracking.

The approved methods for joining copper and aluminum seem to involve either using high-pressure crimps which create a cold weld, or special pressure connectors plus an antioxidant paste or cream which blocks out moisture and thus prevents galvanic corrosion.

I gather it's possible to solder or braze the two metals together, but I don't know what sort of strength the resulting bond will have.

The problems are mostly the different thermal coefficients of expansion
and surface oxidation of Al. Galvanic corrosion can also be an issue.

For more than you probably want to know:

http://www.inspect-ny.com/aluminum/aluminum.htm

If you are talking about your house wiring, the above link will get
you to stuff that addresses the problem.

If you are talking about home brew stuff, the general solution is to
clean, apply anti-oxide grease, and connect under compression, i.e.
something with a tightening screw.

Hello Cecil,

This is the kind of stuff you need.

http://www.niled.fr/Gamme_Niled/PDF/B/PageB06.pdf

You can also connect directly copper and aluminum if you apply (and
maintain) a fair amount of Penetrox P8A (Burndy) all over the joint.

Kind regards,

Philo

Thus our original authur posits: if while driving around, the decaying hegemony of the counter-terrorists up and whisk you off to Ceylon for an interview - and you manage to scrape out of it (Keyed Contradiction), you will have escaped incarceration in the city of Velo (originally Veloceylon, that westerners have regrettably corrupted, as in the original here with Velocity) where static cling, the bane of haberdashers, is notable outside of the monsoon season.

Haberdashers? Static cling? Yes, it is an exceptional reach in vocabulary to answer for noise from the pavement. Join us at rec.radio.amateur.antenna for further examples in this fascinating tour of creative expression.

That is moparholic at twatmale dot cum posting that crap...he got chased into the buhes because we are posting about his faggot crack dealing boyfriend, Randy Chapman, KB5URP. He is a convicted crack dealer who did not think he would be found out, but here's his info...

Sound like David that the rules have been changed and aluminum wiring
has now been banned
because of the things you say are inevitable for failure! I was
unaware that things had got to that point.
Has aluminum been baned for all electrical parts in Industry now,? I
have been out of touch since retiring
but I would have thought that a common connection was a common heat
sink which would alleviate some of the things you point to.
In the court case I refered to it was accepted that if one material
was imbedded into the other such that there was a virgin interface
ther was no problem.
With respect to house wiring I would not have faith in the workman
ship

What is the name of the actual book you are quoting from? Time and
time again we get a quote from books
by some members of this group where it is then used totally out of
context. As an aside I am not quite sure what your intent is to supply
these formula. If it is to substantiate a point then I have totally
missed it.
Many thanks for the postings and efforts

Oooops I have just noticed the book reference. As far as what is
printed I would like to hear somebody say that it confirms my thinking
which is why you brought it forward but you did not say that. Maybe
somebody with mathematical knoweledge will come forward to show how it
disproves what I say
but I doubt that, most will revert to the talking head stance.

Any way Frank I like how things are printed so I will try the library to see if they have a copy. I was particularly interested in the slow wave comment as that was also derided on this newsgroup.
Best regards
Art

Forgot to mention an important point, tho the ball bearing does not come into contact with the tower section bolts it does still has to travel
the conecting tower section points. It is for this reason I settled on the single bearing format. The bearing is usually bolted to a flat surface where the ball is free to move. On the underside of this unit is a seating for a 3/4 dia compression spring which applies a spring loading that is depressed to provide clearance for the tube within a tube joint of the sections such that movement of the "hazer" in terms of rattling is removed. These bearings can be purchased on E bay for about $2.50 a piece
Sorry about the omission in the original description.
Regards
Art

As others have mentioned, there are two issues involved: differing coefficients of thermal expansion and galvanic corrosion. Placing the joint under strong compression is the method of choice for eliminating the thermal expansion problem. Galvanic corrosion is not so simple to solve, however.

Galvanic corrosion, often misnamed "electrolysis", occurs when two (or more) dissimilar metals are brought into electrical contact in the presence of water. When the junction, known as a galvanic couple, forms, one of the metals in the couple becomes the anode (which corrodes faster than it would if the other metal was not present), while the other becomes the cathode (which corrodes slower than it would without the other metal being present). When contact between the dissimilar metals is made, the anode will corrode faster while the corrosion of the cathode will decelerate or even stop. If the terms anode and cathode sound familiar to terms used to describe the electrodes in batteries, they are one and the same. A battery is nothing more than two dissimilar electrodes immersed in a chemically conductive solution. If an external circuit is connected to the anode and cathode of a battery, when the circuit draws current, the anode corrodes. The battery is depleted when the anode is fully corroded away.
We can use a galvanic series of metals to predict which metal will preferentially corrode with respect to the other. Usually presented in a table, the metals are listed in order of most corroded to least corroded. I am including one such table with this post, courtesy of the McNally Institute, 1637 Sand Key Estates Ct., Clearwater, Fl 33767. Note that aluminum is located near the top of the table while copper is near the center. This shows that the aluminum is anodic and will preferentially corrode with respect to copper. There are two major factors that increase the degree of corrosion in any dissimilar metal couple: (1) how far apart the two metals are in the galvanic series. and (2) the ratio of the exposed areas of the cathode metal to the exposed area of the anode metal. The further apart the metals are, and the larger the exposed cathode metal area to the exposed anode area, the faster the anode will corrode. An aluminum rivet in a copper sheet will quickly corrode away, while a copper rivet in an aluminum sheet will show far less corrosion (the corroded aluminum is

spread out over a larger area).

One method of corrosion protection is to use metals close to each other in the galvanic series. The other method is to protect the junction between the metals from moisture. One reader suggested the use of a grease such as Penetrox or Noalox. These compounds, which are carried by most electrical supply houses, are merely fine, irregular-shaped zinc particles in a water resistant grease. When used between aluminum and copper joints, the zinc particles pierce the oxide coatings of both the copper and the aluminum when the joint is placed in compression. The grease keeps moisture out and zinc is very compatible with aluminum; however, the grease and zinc particles do not provide galvanic corrosion protection. These greases are best used in aluminum to aluminum joints. Coating the copper with lead, tin, or lead/tin solder before the joint is made will also provide some degree of protection as these metals or alloy are located between copper and aluminum in the galvanic series. An alloy terminal block that transitions gradually from one alloy to another sounds like a great idea, but it is virtually impossible to make such an alloy. As an example copper aluminum alloys cannot contain more than a few percent copper before the copper precipitates out. Welding, machining, or placing a high copper aluminum alloy under strain can cause microscopic particles of copper to form in the alloy. Localized corrosion will occur around these particles.

As amateur radio operators who encounter aluminum antennas connected to copper feedlines, about the best we can do is use good mechanical contact combined with a protective paint to keep moisture out of a joint. I usually use an acrylic paint as it has superior ultraviolet resistance which is needed if the joint is outdoors. My personal favorite is clear Krylon spray for this use. It lets you seen the joint and any corrosion that is formed. Some joints have held up for more than 15 years in my experience.

1. I encountered dissimilar metal parts which had been joined by what was termed "explosive welding" and/or "explosive bonding" both of which terms show up nicely in Google.

In my case, the parts were cylindrical sleeves, the top of each being stainless steel and the bottom being aluminum. I only saw one (out of thousands) with the bond fractured and I don't know what hit it to break it. They seem quite strong.

Perhaps a vendor of such products has something you can use.

2. I see a lot of brass and darn little corrosion. Would a transition piece of brass be acceptable?

"Sal"

Methinks this might be worth reading:
<http://yarchive.net/electr/galvanic_corrosion.html>
It's a collection of postings about glavanic corrosion with lots of
good info.

Red, yellow, and naval brass as well as aluminum bronze alloys are
marginally anodic with respect to copper so these alloys would provide
minimal corrosion protection. I know it might not be obvious, but steel
would make a better intermediate metal.

This will make sense if the actual voltages are included in the galvanic
series. These voltages are in sea water and with respect to a standard
calomel electrode.

Zinc -0.98 to -1.03
volts
Aluminum -0.70 to -0.90 "

Cast Iron -0.60 to -0.72
"
Steel -0.60 to -0.70
"
Red Brass, Yellow Brass, Naval Bross,
Aluminum Bronze -0.30 to -0.40 "
Copper -0.28 to -0.36
"

As a non engineer and somebody who is wired diferntly from the norm
it is undestandable that you have problems with Maxwell equations.
Gaus did contriubute to the Maxwellian laws which is accepted. The
static law wsas not
the particular gaussian contribution. Many have taken this that tho
Gauss contributed to
Maxwells laws it was not by way of his law of statics thus some have
taken this as pointing
to statics as something different and separate from electromechanics,
Science has excepted that
equilibrium is as universal as the GUT theorem which is why Einstein
searched so long to identify
the "weak" force. I remember a decade ago where I pointed to water
cavitation having the same
effect in electrical matters pointing to the comnbines loop dipole
arrangement where cavitation
occurs so that voltage can be a maximum at the dipole ends and where
llewellen quickly pointed
out that electricity does not work that way likening it to pushing to
a new science. am totally unaware
and nobody has pointed otherwise that the law of statics had a
deinitive connection to Maxwells laws
which points to radiators of a smaller volume and the identification
of the weak force. You can gabble forever
in knee jerk reaction to my postings but until you provide scientific
technology to the subject to repudiate what I state
you will remain a person that is wired diffgerently from other males
that communicats in a strange
way such gthat all meaning is totally obscurred in your search for

like minded people thatg you can have a close relationship with
in a like minded way. I for one are not one of that life style so get
off my back.

Frank
What you have done is to bring to the fore front modern thinking in
science that has emerged since
the thinking of Jackson and Termin and become nmore in line with
Einstein and particle theory.
It without doubt confirms the thinking of the Grand universal theory
by the inclusion of Staic law
tho without the conclusive proof that Gauss;s static law provides but
even so arrives at a common conclusion.
It plkeases me very much that it is now used in college education so
that the present generation will not bemind bound
by the past. I was especially pleased with the reference to "slow
wave" which is a very importabt component to Maxwells laws
that has been ommited in the past. Regardles that the author did not
reference specifically the statics law he is very implicite
with respect to the commonality of statics with with respect with
electro magnetics which I thank you very much for bringing it to the
attention of others.
This follows your effots in showing that NEC computor programs do
indeed support the idea of arrays in equilibrium when you provided a
computor analysis showing radiators that were resonant and at
different angles to each other because of the addfition of the angle
requirement of the weak force.
You are to be commended for studying the statements for yourself to
confirm their veracity instead of the attitude of the talking heads.,
I look forward to your future posts
Very best regards
Art Unwin KB9MZ.......XG

Well, Authru, it is obvious to the readers of this thread that of the
two of us, this non engineer is the one who better comprehends
Maxwell's work!

This non engineer easily observes that Maxwell contributed the
variable t (for time) to Gauss' equations. It is directly observable
on page:
http://www3.telus.net/nighttrainexpress/maxwell_1.htm
at the paragraph heading (guess what?):
"The Time-Dependant Wave Equation"
This is a part of the curriculum of every EE who has attempted to
educate you to this matter. Even this non engineer has formal
training to this specific point.

You now have been offered clear, specific, and demonstrable proof that
your claims are spurious. However, I am full aware that we will
revisit those invalid claims again as if you were never aware of this
simple demonstration.

David, I am so happy that Dr Davis of MIT has finaly been vindicated
in the eyes of this group.
It has taken years for the group to accept the static relationship
with electromagnetics.,
I am also pleased that the present generation are using up to date
material and not the books of 50 years ago
where those taught at that time all was thought to be known and all
change was resisted. Of course if this newsgroup wish to challenge the
book excerpts that have been placed on this thread it would be very
interesting including the deduction that a radiator can be any size,
shape or elevation as long as it is in equilibrium.which is no small
matter in designing small volume antennas using all four fourses that
Maxwell and others clearly intended. Antennas belong to the present
generation where the old timers are satified going to their graves
convident that all is known while the present generation forgve ahead
by the recognition of the trole of all four fouces which must be
accounted for in any full analysis of the subject of radiation.. Now
that Dr Davis has been vindicated old timers who are still mentally
capable have the opportunity to be present in these very exciting
times
Nice weather here Davis so put aside that book you are writing and get
outside where you can practice the praticle instead of being a talking
head.
Best regards
Art.
PS I look forward to your destruction of the text suplied on this
thread since it opposes everything you have argued for during the last
half dozen years.
Hate to tell you but I did tell you so, many, many times. Eat some
humble pie!

If there isn't already, stuff a short hunk of something solid like a fiberglass rod or wood dowel in the end where you make the connection, put terminals on the wires, use stainless screws with star lock washers under the screw head and between the terminal and tubing and the terminal and nut, anti-oxide grease, overwrap with sealing tape then with regular tape.

That's how I connected to the vertical in the middle of my lawn where the sprinklers hit it about a decade ago and there have been no problems.

FWIW, I tried brass (because someone gave me a bunch) for this sort of thing and switched to stainless.

Always use Antenna Grease or equivalent on Aluminum contact points to keep the oxidation and moisture out. Steel is subject to rusting, so Stainless Steel or Galvanized Steel is best for antenna hardware to clamp to the Aluminum, and use tinned Brass or Copper loop-eye terminals soldered to the Copper wire and bolted with Stainless Steel or Galvanized hardware. Stainless should have a little Petroleum Jelly, NoAlox or Antenna Grease to keep threads from seizing. I have used Stainless Steel hose clamps and they work fine for quite a while.

Aluminum house wiring has been banned a lot of places and is a bad idea all around.
The problem is that the Aluminum is weaker. As it is flexed and heated at the connections, it will migrate out and the connection will get loose and you will have a cascade of oxidation and increased resistance. The recommended answer for that failure (If your house didn't burn) was to use a copper wire pigtail out to a wire-nut connection to the existing Aluminum wire with no-alox in the mix. Obviously, there is a loss of integrity and

"how to jam the wire nuts into the box" issues. If you have Aluminum house wiring, you should keep an eye on line drops all through the house and run new wiring for any big draw appliance addition.

Nothing wrong with that David the maximum boom length I got to was 80
feet and 13 elements
but then had to back off to 60feet but they surely worked good but
now
I have got to old to handle the work required to maintain them.
I was very surprized to hear you say that you were wired like Richard
so don't ventue in Illinois!
By the way did you get your four square antenna sorted out and is it
working to your expectations?
With respect to antenna height I have a feeling that height is not a
question of wavelengths but a question of
capacitive coupling to ground. I put the top band antenna up
temporarily at a height of thirty feet and the
the impedance settled on 50 ohms. I am now winterizing it so it gets
thru the winter. It consists of just one element
and a dish reflector but it will have to wait until next year before I
feed it at the dish end, in the mean time it will just be fed at the
centre
I still hope for directionality even tho the rotor is at 30 feet but
either way it will be interesting unless I move on to another project.
I had to move away from the shoebox size of antenna, what I found out
was it worked quite well for receiving but for transmit the eddy
currents opposed each other thus preventing particle elevation so the
volume is now double what it was but still small enough for the rotor
to turn the top band form and light enough to easily put it on the
tower

Thiking about the above subject I revert to the Gaussian field
aproach.
Everything in this Universe has it's own arbitrary border which must
include the Aether
otherwise if this was not so the arbitrary borders of the Earth,Sun
and other items
would have arbitrary borders that would abut each other. Since the
aether has an arbitrary border of its own it must be connected to
galactic particles and charges in equiulibrium. With the Suns
eruptions and other changes in particle distribution the passage of
particles into the arbitrary border would be never ending as would be
the escape of same which sugests a swirl of particles in orbit is what
constitutes the Aether. I understand the space program has confirmed
the presence ofmany different particles in the aether such as the
neutrinos from the Sun but I have not heard of the number or
identification of other particles that exist.Since within the aether
there is considerable number of particles with a high density I would
have thought the space program would have brought back some data with
respect to the Aether constituents and the orbit modes. Anybody have
any info on that? I am assuming the neutrinos are not part of the
orbiting particle mass but I may be wrong in that assumption, tho
these particles would only have 1/2 spin if any! Most certainly the
other type particles would not be diamagnetic otherwise neutrinos
would be part of the orbiting mass and probably contains all four
forces of the Universe including a gravitational pull e.t.c.

I'm sure it will be directive to some degree. But except for receive,
what good will that do you if you are 20db-30db down from a dipole
due to the excessive inductive losses?
I liken your setup to using a MW receiving loopstick as a transmit
antenna.. :/ Not a whole heck of a lot of difference except yours
is now a massive four shoe boxes in size. Mercy..
It's still puny considering the frequency.
My MW receiving loop in this room is bigger than that.
"A diamond 44 inches by 44 inches.
And my MW loop would almost certainly outdo your design
being as it is bigger and uses less turns of coil. "5"
It's still a dummy load on a rotating stick... :/

So we have validation that your first antenna was a dud when used
for transmitting! I'll alert the SPCA!
But I'm afraid doubling the size of your dummy load on a stick is
not going to pan out in the manner you would like.
Even four shoe boxes worth of wound wire maketh not a good 160m
antenna.
Reboot and try again.

Oh, I read a lot including scientific american but I don't soak up
things as fact.
Now that I have stumbled upon static particles and Neutrinos I look at
things in a different light and from my own perspective
For instance I easily can see the updraft of moisture also including
neutrinos
which becomes a lightning discharge as the moisture changes in
temperature and forming ice
where the neutrinos clump and return to earth in a strike containing a
magnetic field which can be seen asd totally disabling any compass
needle
as well as the
circular currents created to form tornadoes and whirlpools just as
eddy currfents are created.
I see all nature as being a similar phenomina from the four forces
whether mechanical, electrical or chemical
all of which eminates from particles with charge and their own
magnetic field. These thinkings may not all be correct
but with my confidence of how radiation is created to me it is only
natural to see if these same effects exist
in other Universl phenomina which to me are clones of basic phenomin a
of nature. Yes I read a lot but I never accept things as gospel as
history shows that it takes more than one shot to solve a jigsaw
puzzle where the individual parts do not have picture until all is put
in place.where on the road to understanding we have lots of differents
knoweledge areas that interconnect in many places but is only held
together by a theory that also has a paradox Spme would call this an
out of the box thinker which industry seeks in terms of diversity that
oft times provide a different aspect to solve a problem.

Maybe that is why I was invited with my family to the USA. This sort of thinking has now produced a antenna that is factual and not a approximation as all antennas are today. Yes it was found by accident by me when retracing the routes of the masters rather thasn acceptance at face value but by the understanding from first principles with the advances of the day which the masters did not have which often means that I assign different names to the norm

now that will put some researchers out on their buns after a lifes worth of
work studying lighting as electrons. its only neutrinos, they have been
barking up the wrong tree all along, the first 'masters' studied lightning
and static electricity they understood it to be movement of electrons, but
they were all wrong. even gauss must be wrong now since his fields are
based on the same static charges caused by electrons and protrons.
neutrinos have no charge, their motion can not cause a magnetic field, nor
do they cause tornadoes. thanks for a good laugh on an otherwise dull day.

Interesting but the neutrinos can obtain a charge when entering the
Aether
which in itself I see as a magnetic field of particles enclosed by an
arbtrary border.
When one complets the math of comparing Gauss's law of static compared
with
his law of magnetics contained in Maxwell's laws it is not enough to
leave it at that,
a single mathematical excercize you must go on and compare with other
phenomina and physics matrhematics so your fi8ndings do not clash with
known and accepted phenomina
where substitution of ones findings can be inserted into other
accepted physics formula in terms of interconnecting
truth. Tbhus my findings have to supported by the mathematics in form
of substitutions in accepted and existing formula
as well as in the experimental trail. Thus my work has to be extended
not only by experimental results but also
via substitution in other formular excercised in other areas, this

took time but eventually I succeeded.
As far as the weather is concerned what creats lightning or tornadoes
and many other things have not been previously explained
such that they would be verified from another direction that includes
my findings.
So my thinking are not just idle thought but an effort to match my
physics findings with those of others an d this ofcourse includes the
identification of all four forces of the universe so advances can be
made on a solid foundation.
Weather is a bit chilly but not cold enough to prevent tower and
antenna work

Dave,

You interpret his quote too broadly (understandable given the murk
that has to be penetrated). If you re-read the quote you offer, it
offers absolutely nothing that distinguishes the participation of
neutrinos in the process.

Neutrinos don't
1. constitute a current (they are neutral!);
2. become a lightning discharge (they go for the ride!);
3. have a magnetic field (they don't have a charge!);
4. upset a compass (they are inert!);
5. create currents (they don't have any mass!);
6. form tornadoes and whirlpools (not enough magik!).

Basically, neutrinos are freeloading bums whose only accomplishment is
to queue up for a dole. If they move with a current (which is
doubtful given their aversion to work), it is like a hobo riding the

rails. To say a hobo runs the nation's railroads is equally absurd. Neutrinos cannot even summon up a charge where the panhandler on the street is far more productive.

Neutrinos only rub shoulders with the doers and shakers (electrons and ions) so that they can seem important by association. This is why they are the pathetic cousin in physics who have to be flung at high speeds into targets to get them to perform any form of useful work.

Neutrinos remind me of the time when Hare Krishnas, to look mystical and spiritual, danced and clanged their cymbals in airports for spare change.

Trying to offer neutrinos as important is the intellectual equivalent of portraying skid-row as the Valhalla of learning.

David
You must read and understant the "electromagnetic properties of
Neutrinos"
which is up to date. You should be able to google it. In the last
decade many new facts have come to light with respect to Neutrinos
which is in fact driving the huge expeditures at CERN.
There are a lot of people usually older people who rely on the books
they used in college
50 years ago such they feel all is known and therefore do not keep up
with studies since money becomes
the replacement. If you google the title I gave you it will bring you
up to date within a year or so which will
allow you to weed out old assertions uttered by those who have retired
from study.
If it is dismal and cold in Michigan then make use of the evening by
reading up on the subject to get up to date
Regards
Art

"Because neutrinos are very weakly interacting, neutrino detectors
must be very large in order to detect a significant number of
neutrinos."

It would seem that the detector (and the corresponding transmitter) of
neutrinos would have to be larger than a shoe box, or two. In fact,
the size of CERN (that is, afterall, why they built it) which is
"with a diameter of 2 kilometres built in a tunnel"
would scarce lift the S-Meter off its peg.

Reading about these lazy welfare queens of physics may be entertaining
on a cold winter's night, but throwing a few bajillion in the
fireplace won't add one calorie of warmth.

Hi Sal,

As an instrumentation designer who worked mainly in the chemical industry, corrosion abatement and material selection were daily facts of life. On more than one occasion, the company metallurgists saved my rear end. For example, stainless steel can be both cathodic and anodic with respect to itself. While most folks consider stainless a panacea for corrosion problems, it is not. In fact stainless alloys have little resistance to salt water. There are many poor owners of stainless auto exhaust systems that learn this the hard way when streets are salted in the winter to melt ice. Copper, brass, and bronze alloys are used in marine environments because of their anti-biofouling properties (barnacles, coral, mussels, etc.).

I try to make my posts educational when I can. Thanks for telling me that you had seen these numbers before. I hope they made a little sense this time. I think if we all were back in school, we might pay more attention this time. I know I would!

David
Pull yourself together.
Neutrons ARE a form of electrons. (leptons)
Neutrons are not within the arbitrary boundary provided by Gauss
Neutrons DO contain charge
It is assumed there are anti neutrons because they are suspected of
being rotating dipoles
this because they have a magnetic field
Yes they do have a magnetic field
They are attracted to diamagnetic materials as free electrons where
they do not become absorbed.
Detectors were placed underground on the ASSUMPTION that they passed
thru earth without stopping
Updrafts in storms suck up diamagnetic materials which include
neutrinos, frogs and the like
Take away the moisture that they rest upon until the resting density
is high whence they return to the Earth
mainly a diamagnetic material.

And it goes on and on.
Please read up on the properties of Neutrons as there has been a lot found out in Japan, U.S. and other places
in the last few years that have turned the info on Neutrons on its head.
Old books are just not up to date
Regards
Art
Lightning strikes or the descent of charged particles will send nearby magnets haywire.
Detectors of heavy water are large in area because the size/mass of neutrinos is so small.
Cern is applying high speed to neutrinos purely to obtain an impact of such power that it will
provide details

Jim, where does this information come from?. To my unqualified mind it
appears to be some what dated
possibly back to the the time that neutrnos was considered to be
without mass!

For a neutrino, certainly. No charge to repel, no mass to get in the
way, no interference because it is unattractive (like a sidewalk wino
on a Saturday night... the "Lost Weekend" of particle physics).
Neutrino: an electron without cojones;
a proton without that wild thang.

Who would sit up nights waiting for a phone call (-um- radio program)
from a Neutrino?

While I am at it the particle that I refer to may well not be a
neutrinos
but it does seem to fit. Neutrons and all the other chemical particles
that I have negligently brought into the subject
do not have a place in my theory with respect to radiation
just a particle which I feel inclined to call a Neutrinos
I say this for archive purposes so the error that I have been making
in my typing
is cleared for the record
Thanks Cecil

Just about anywhere one would care to look.

None of the above information has changed in the slightest since many
decades before the 1998 Super-Kamiokande neutrino detector results.

Current thinking is that neutrinos have a mass on the order of 0.1 eV.

The mass of an electron for comparison is about 0.5 MeV.

>where those taught at that time all was thought to be known and all
>change was resisted.

Art, I am not sure what you mean. This material has not changed
in over 100 years. To quote from Ida's text, pp 731, 732: "Based
on the inroduction of the displacement currents in Ampere's law,
Maxwell predicted the existence of propagating waves, a prediction
that was verified experimetally in 1888 by Heinrich Hertz. This prediction
was based on the nature of the equations one obtains by using Maxwell's
equations. We will show here that Maxwell's equations result, in general,
in wave equations". This proof is shown in "Example 12.3", which is
posted on my previously referenced web link:
http://www3.telus.net/nighttrainexpress/maxwell_1.htm
Unless you can show, by manipulation of Maxwell's equations, that it
is possible to obtain a 2nd order partial differential equation where the
independant variable is time; what is the point? I should also note
that a course I took in electromagetics (About 1983) has an almost
identical development of a wave equation. For reference the text is:
"Introduction to Electromagnetic Fields", Clayton R Paul, and
Syed A Nasar, published in 1982, ISBN 0-07-045884-7, pp 241 - 243

73,

Frank.

>>>
>>> proton: classification baryon, electric charge 1.6 X 10-19 C

I wonder if Art meant to say "Neutrinos ARE a form of electrons.
(leptons)".

That would be closer to the truth than what was actually quoted above,
in that electrons and neutrinos are both leptons.

It's still incorrect, though, according to the definitions I've read.
Although neutrinos and electrons are both leptons, that doesn't mean
that "neutrinos are a form of electrons".

By analogy: dogs and cats are both mammals. That doesn't mean that
dogs are a type of cat, or that cats are a type of dog.

For what it's worth - I have seen no evidence at all to indicate that
flows of neutrinos have anything whatsoever to do with the behavior of
antennas or with the transfer of electromagnetic energy from/to
antennas and/or free space.

That pretty much tosses out the baby with the bathwater.

>just a particle which I feel inclined to call a Neutrinos

So, you now claim to have invented/discovered an unknown particle that
you are going to name a Neutrinos? (Convention would probably bristle
at adding just an s makes it respectable science.) Is this a
creationist particle?

Why not call it an Artrino or Unwintron? How did you discover it?
What did you use as a detector? Were you listening to 160M when it
came on with a signature tune like Big Ben and the BBC?

I'll bet you would. <G>

Seriously, just kidding and no offense intended.

I have some old CB stuff that I used in the Seventies. It appalls me just how little this gear brings on the used market.

If I had a non working HF rig, I'd give it to you. It wouldn't be the first time that I've given a rig away just to get someone up and running on the ham bands. After all, lots of people helped me out and I still appreciate it.

4251. SM0VPO Homepages - update

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-10 21:32:30 UTC
From: Harry Lippitz <johnsmith@micro$oft.com>
Message-ID: <OL1Sk.3974$U5.25888@newsb.telia.net>
Source record: 20325

Hi all,

A few things have happened since my last update. The homepages are to be found at http://web.telia.com/~u85920178/ where there are some 250+ projects, many with PCB foil patterns in BMP format, 250 dpi. This means you do not need any special software to view it.

The last antenna was a 145MHz colinear stuffed up plastic drainpipe. Hell of a gain, but it needs support. The only problem with it is that under stron sunlight the plastic pipe bends away from the sun!

The lastest project was DIY transformers. the link is http://web.telia.com/~u85920178/power/diy_transformers.htm and it uses those cheap transformers from http://www.kjell.com

I also did an article on diode switching basics, but this I also translated into Swedish and sent to the SSA for publication. The URL for the original article is http://web.telia.com/~u85920178/data/diode_switching_01.htm

The old messageboard is now defunkt - kaput - deceased. Instyead I have a nice new forum at http://sm0vpo.wahlberg.cc but you should bookmark the address http://web.telia.com/~u85920178/board.htm so that I can again change in the future. The new board is hosted by Magnus Wahlberg in Eskilstuna, and a fine thing it is too. Message at the bottom do not just drop off into space. Old messages stay there until I or a moderator deletes them.

Perhaps you never thought about it, but the old formula for frequency = 1 / 2 x Pi x Root(LC), and the only variables are F, L and C. So for any value of F you can build a table of Root(LC) values. For example an index of 1MHz = 25000. If you divide 25000 by 250pf you need 25000/250 = 100uH for resonance.The value for 2MHz is 6250, so if you subtract one index from the other, you can work out the variable capacitor you need to track tuning between the two frequencies. The article is at http://web.telia.com/~u85920178/data/tune_01.htm

Future articles are many and I have several that are all nearing completion. Progress is interrupted by a speeding ticket with one of those stooopid speed cameras. Now I know how they function I will shortly be publishing a speed-camera blocker. I will also offer a few in kit form, until I get my 2400:- back.

I have also finished a "Generating 230V AC Power in 5 Minutes" video film. The link is at http://www.youtube.com/watch?v=t3yvdXIjGSo

Best regards to all from Harry - SM0VPO

Frank, a couple of years ago I explained the inter weaving of Gauss
law of statics
with that of Maxwell. I twas this that met the most resistance of the
this group.
They seemed to see staics as something divorced from electromagnetics
and thus
one could not use equations of one with respect to the other. Thus
when it was shown
that the statics mathematics equated with Maxwells laws every body
said that was not valid.
The text you supplied made specific reference to this mathematical
interplay whilst talking about quasi
statics tho they never did the interface that I did. It was this
rejection at the beginning that set the stage
for years long rebuttle to the ideas that I put forward. To this day
pretty much all are of the position that interfacing

statics with dynamic fields or time varying currents was totally invalid which I put down to the education they received some 50 years ago.
It was for that reason I was delighted to see a modern book that treated the subject with startling clarity.
About 2 years ago a white paper was put out by two scientists that covers the Aether and its driving relationship
to the Universe as well as revisiting the thinkings of the past with which they outlined questions that the present aproach
seem to gloss over, as well as the revolving constituents(not foam) of the fast moving and revolving Aether and comparing present day notions
of the Univers as opposed to their own findings. This paper is excellent and shows that many present day notions could be way of the mark
Thus it pleases me that many are still questioning or reviewing the logic of electromagnetics including the more modern works of Planck in light of present day advances which certainly does not reflect the attitude of many in this group. In science and physics it is not a crime to challenge the thinkings of the past regardless if it may result in change as age of a theory does not present the idea of validity goes along with seniority
As an aside modern books still refer to waves in electromagnetics but I feel this is a result of not understanding how radiation occurs and thus concluding it similar to magnetic lines of force where as I theorise it is the multi quantity of elevation and projection of charged particles with spin such that straight line trajectory is maintained , a must for transmission of radio communications by virtue of the "weak force"
Regards
Art

4253. Shellac, varnish, parrafin wax for wood feedline spacers?

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-10 21:48:29 UTC
From: Tim Shoppa <shoppa@trailing-edge.com>
Message-ID: <998b7488-3722-483b-a325-b0bbb75389c6@w24g2000prd.googlegroups.com>
Source record: 20327

I've had my all-band-doublet up at 90 feet for over a year now with ladder-line spacers cut from polycarbonate sheet. Works great, is kinda pretty in the right light. The polycarbonate is supposed to be relatively UV-resistant and it seems to be doing pretty good.

But I have a hankering to use wooden insulators next time I put an antenna up.

The old ARRL handbooks always recommended boiling wooden feedline spacers in paraffin wax for weatherproofing. I suppose the idea is that it's water-repellent. Don't know how long this can be expected to survive weather extremes (ice, heat). In my experiments in my garage, the wax coating seems to pretty much rub right off with my fingernail, so I'm not sure how much good it does where the feed wires or tie wires abrades against it.

Shellac is another option I suppose, but shellac seems to me to be something like the enamel coating on magnet wire, and having used this in rooftop antennas in the past I was quite surprised that in the summer it gets hot enough up there to burn off the enamel.

Spar varnish seems to be the ultimate in wood coatings for weather resistance.

Any words of wisdom? Or is polycarbonate really the cat's meow?

Having fabricated antenna stuff out of both plexiglass and polycarbonate over the years, I am very very impressed with polycarbonate's workability. It does not craze or crack the way that plexiglass does.

Howdy,

I've been using electric fence crimp terminals from Dare.
They're sold in numerous farm and hardware stores. There's
a crimper marketed by Dare for them as well at a very reasonable
price.

They're actually Nicopress terminals. Look like lead plated
copper to me. I've joined wire of various materials with
these including, aluminum to galvanized steel, aluminum to copper
and copper to galvanized steel. They do a fantastic job.

It is NEVER gonna stop, moparhoLICK...NEVER. Get used to it. You can do not a friggin' thing to stop it. HAHAHAHAHHA...ASSCLOWN...sit there and do what you do with truckers...SUCK ON IT! LOL! The more you post the more we will whap your faggy face with your gay lover Chapwoman's deal. Go eat a kitty turd and get over it, queenie.

I don't understand the above comments since Gauss' laws for electric
and magnetic fields are the 3rd and 4th of Maxwell's equations. In
fact the equations for static and the time-varying case are identical,
as follows, in point form:

DEL dot D = rho, and;

DEL dot B = 0

(Paul and Nasar, pp 199, 200.)

The above is identical to that found in the classic EM text:
"Electromagnetic Theory", by Julius Adams Stratton of MIT; published
in 1941. There is nothing new in any of this.
Probably the development of a wave equation from Maxwell's
equation was a bit of overkill to make a point.

The "Quasi-static" referred to above only effect displacement
current in Ampere's law.

I think if you're using an older transmitter - keep up the retro theme by
boiling the wood spacers in parafin like the old book says. (But I would
bake them at 190degrees for an hour to remove all moisture first.)

I would also be tempted (considering your home-making the feed line anyway)
to try what I recall being called "G-line", where on the transmitter end of
the line you keep increasing the spacing then just drop one line - and you
have only one conductor going up.
then of course, you do the same thing at the antenna end, going from
2-conductoe wide spacing to 'normal spacing'.
Experiment.
Report back on how it went.

Brilliant Frank as a mechanical engineer I trust you will excuse me
from knowing this.
Ofcourse I will have to review things for myself so I understand fully
what you have pointed out
The way I put it initially is that if you add radiators and a time
varying field to a gaussian field while holding to the
equilibrium format you arrive at Maxwells law. I asked somebody that
was knoweledgable in the field about it and he stated I had made a
discovery
which now looking back could mean anything.However, I sought this
opinion from a qualified person as I had gone thru a series of
illnesses and at that particular meeting puss was flowing from my
pacemaker chest pocket but it was an excercise that I had to do since
my training originially was that of an mechanical engineer before I
had heart troubles and lost some of my memory faculties Because of
this "discovery" it then becomes obvious that a radiator can be any
shape , size and elevation
when meeting Maxwells laws" as long as the contents of the border is
in equilibrium" Now Frank notable hams have stated that a radiator
must be straight for maximum efficiency which from my observations are
untrue. Knowing that modern day computor programs were formulated
around Maxwells laws
THAT INCLUDE THE WEAK FORCE it would appear an overcheck of the
equilibrium factor should appear when using an optimizer. Well as you
know you overchecked that for yourself and confirmed it, thus the
basis for my theory then started to unravel until I arrived at my
present point where antennas of the highest efficiency can made within
the smaller volume which I have subsequently made many. So it was then
I shared some details to this group as they were supposed experts and
from then on they have thrashed me in every way including a ham who
provided the matjhematics comparing
Gauss and Maxwell which continues to this day.Basicalyl all resisted
the idea of a different antenna design on the assumption that all was
known about antennas Now we have assertions that the Neutrinos has no
mass and no magnetic field and yet itis understood that there are
millions of them for every cubic metre on Earth and it goes on.
Hopefully the above will make things clearer. I will try and get back
to the white papers that I spoke of and hopefully the book that was
published later. I will get back to you after I review the history of

events on my laptop in the hope it still resides there
Best regards
Art Unwin KB9MZ....XG

Just one word of advice. The vapor of boiling paraffin is extremely flammable -- I'd guess about like gasoline -- so be extremely careful if you use the old time method. At the very least I'd do it outside and over an electric hot plate rather than an open flame.

Roy Lewallen, W7EL

Not precisely true in the case of InSAR.. One transmitter, two
receivers. A Tx and Rx can share, but the second receiver needs its own
antenna. (Modern phased arrays can segment a long array into two receive
arrays to do InSAR, as well).

the SPY-1 isn't a SAR (well.. it might be able to do ISAR if the target
is moving or rotating) but it does use the same aperture for Tx and Rx.
(Racks and Racks of L band T/R modules)

Almost all modern radars send some sort of PN coded pulse (e.g. a Barker
code) to be used in pulse compression so the peak/average power ratio is
limited. A few radars use linear FM chirps.

Dave
Any AO programs will do it as they both have optimizers
There is a free program Gal-mana or some thing like that which also
has an optimizer
4nec2 is a freebee with optimizer. All of these will provide antennas
in equilibrium
All other antenna programs have inut of the weak force tho I doubt
that those designed
just for Yagis will have it as that is a planar device. My
suggestion is that you stay with minninec programs
and the 4nec2 program by Ari which incorporate Minninec optimizers
additions.
I would imagine that any history books on universal laws would have
reference to it.
The masters worked from basics to get their laws based on equilibrium
which in the mathematical areana is a Gaussian field where all forces
must
add up to zero. All of the laws ddid not add up to zero so they added
a force that completed the circle. They did not identify the "weak
force" but inclusion was a must for all forces/vectors to add up to
zero.All the laws that Maxwell used in his condensation of laws all
had the stipulation of equilibrium.
Wet and cold here so stay in and be a book worm
Regards
Art

"
David I googled" Maxwell equilibrium"

On the first page they have a wiki answer to a question as to why
equilibrium is not a basic for fractional wavelength antennas!
You can kill two birds with one stone on that one

A Google search with that phrase returns several papers on the solution
of Vlasov-Maxwell equations for a plasma, which has nothing to do
with antennas.

A Google Groups search with that phrase returns numorous links to
your own babbling nonsense.

4283. Stacking beams

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-12 07:15:37 UTC
From: Gary Smith <vk3lcd@gmail.com>
Message-ID: <gfdvtbqrr1@news-01.bur.connect.com.au>
Source record: 20407

Hi, i am going in a VHF/UHF contest this weekend and have a question about stacking beams.
We will have a pole approx 15-20ft long and want to stack the following antennas,

1x20 element UHF yagi
1x10 element 2 Metre Yagi
1x5 element 6 Metre Yagi.

UHF yagi is approx 6-8ft long
VHF is approx 6ft long
6M is approx 17ft long

They are all horisontally mounted. I am guessing it will be UHF at top, then 2 mtr then 6 mtr.
What i would like to know is if this pole is long enough to space them vertically enough or not.
If so, what distance should they be?

Thanks

Gary
VK3LCD

Hello, and I would like to propose that subjects in the area of general electromagnetics be posted to a more appropriate ng such as sci.physics.electromagnetics or sci.physics.research (moderated). I think Mr. Unwin has a better chance of finding more sympathetic ears to his propositions in a more theoretical venue. Along with that recommendation goes a quote from the late Carl Sagan: "Extraordinary claims require extraordinary proof." Sincerely, and 73s from N4GGO,

It should work. Try to get at least a 1/4 wavelength between them (a half wavelength would be better. If you can get the 50 MHz 3 meters off the ground and the 70 CM on top, and split the difference with the 2 meters, it should be a good place to start. Do you have a VSWR meter e.g. MFJ-956?

Wikianswers statement referred to
The question raised was that Maxwells laws require equilibrium
Full wave antennas are in equilibrium buf fractional wavelengths are

not.
(((((((!!!!!(Seems like I have heard that a lot on this
newsgroup)))))!!!!!~
The answer was basically in agreement and stated that for fractional
wavelength antennas
requires compromises when applying Maxwell laws..
You can now ask where the curfrent goes when it reaches the end of a
fractional
wavelength radiatorand get what some say "is the rest of the story"
On the other side you can bombard Wilkianswers that HAM RADIO REJECT
the idea of associating equilibrium with Maxwells laws or any other
laws in Physics.as it just blabber
and does NOT represent the present day thinking of ham radio
enthusiasts in the U.S.and the American Navy reseach centers
in Washington DC
You, the experts, can also ask the ARRL to print same in QST otherwise
change will become unstopable
Regards
Art

I would like to add:

Gaining the "extraordinary proof[s]" to validate "extraordinary claims"
requires the extraordinary pissing-off of personalities who are deeply
rooted in common knowledge/theory/equations/accepted-beliefs/etc. -- JS

But then, a "tempest in a teapot" would, quite likely, result in the
same action(s.) Ya' never know, ya' just never know ...

Regards,
JS

Current is always zero at the end of a radiator of any length.

Maybe Frank but it never came to a stop!!!!.
When you look at it as not being equilibrium one must show the sharges
moving to the ends of the radiator
where end effect is created. Now you draw a line to the right on the
outside of the radiator with an arrow at the end to show the movement
of the charge.
Now the original notion that there is no charge or current goes away
because a reactive line and arrow must be assigned for quasi
equilibrium
to be established and that line or vector has only the center of the
radiator to flow to form a closed circuit.
When a radiator is in equilibrium the charge does NOT move to the end
so that there is no vector to the right
thus physics state that the need for an opposing vector does not
exist. Thus for a radiator in equilibrium current will move along the
surface but the charges will not. So do the charges really stay in a
static possition? No it doesn't It was on the surface over the skin
provided by the eddy current which when combined with moving current
both produce a combination magnetic field that provides a vector force
away from the surface of the radiator.
The charge static position.is thus over powered by the combination
magnetic field that places a spin upon the partiucle and ejects it in
a straight line trajectory. These ejections have a reberatory effect
on the radiator and also on the receiving radiator so that
communication occurs in a vibratory manner
Now the extension of gaussian static field shows up in actual
radiation phenomina in the same way the eddy current fields provide
levitation which thus agrees with other known laws Tho it can be shown
that the law of statics is part of Maxwells laws mathematically I know
of no disclosure where the same was approached from a strictly flux
flow position which brings static particles into the mode of radiation
as well as defining the eddy current creating the "weak" force as
anticipated by Einstein till he died.Nowhere is a physics law violated
physics laws have been solidified and the theory is solid
Best regards

Again you are misquoting and this time it is Planck
His constant evolved around a proton where the results has some
conflicts to this day
with respect to classical science. When he was studying black holes in
the aether he saw it as PROTONS escaping
and not particles such as neutrinos which have since proven to have
mass where he was using the term momentum which is a varient of mass
and gravitational effects. There is nothing that suggests that energy
can be carried without the presence of mass and thus the wave of
energy as inferred by many is debunked, Yes Maxwell left a lot but he

nevver alluded to static particles and piossibly not even to the pre condition pf equilibrium.
What he is famous for is noting all the observations and equations of his predecessors and used his mathematical acumen to reduce or condense the laws given to him of which he did not individually contribute as personal observations at that particular time. Gauss specifically mentioned static particles where
Maxwell omitted such references thus leaving radiation as a mystery where the "wave" format gained strength because of the magnetic field format b ut with which Einstein disagreed. Einsteins foray into relativity further debunked the idea of waves or energy without mass to carry potential energy or to
show the effects of kinetic energy and the association between gravity and momentum and the importance of frequency of movement.

You cannot rely on the forever continuance of old books that were used in your part of the centuries as being imbedded in stone based on your own particular life span.History shows that new generations come along using the education of their fore fathers on whose shoulders they stand and where the human race requires challenge that the past may or may not accept when their time comes about and thoughts go with them. Remember a constant as used by Planck is purely a mathematical condition which describes an event that occurrs physically without change such that a number can be prented in the place of a full description of the actual event in a similar way the "wek force" has been calculatedf for the past century.

The charges (electrons) do not realy move. They vibrate
at the applied E-field frequency. The charge displacement,
depending on frequency; for example at 10 MHz, is of the
order of 10 atomic diameters -- approximately 2*10^(-9) m.

There seems to be too many elements on the VHF and UHF antennas. I wold
think the booms should be twice as long.

I did not have too much choice when I mounted my antennas on the tower. I
had about 15 feet of pipe out of the top of the tower. I put a M2 432
antenna at the top, went down 4 feet and put a M2 2 meter beam, both had
about a 14 foot long boom. Then 5 feet below that is a 5 element 6 meter
beam on an 18 foot boom and then the triband beam for the low bands. I am
sure they interact to some extent, but they do seem to work ok and not much
interaction of the swr when mounted on the tower. All beams are horizontal.

Didn't the weak force and the electromagnetic force get
united into the "electroweak" force in the late 60's?
In which case, aren't the two forces interchangable?

Yes tho some use the term electroweak incorrectly as equal to the weak force aloneinstead of the combination force (I may have described that incorrectly).
Some have now reduced the number of forces down to three where some also infere
that it can be reduced to one.(gravity being a subset of electromagnetism) Problem is that electroweak bundles the mathematical terms
as if the weak force is the only other action whereas the weak force is a bundling of all mathematical factors(a constant by any other name)
required in addition to the other forces to allow all forces to sum to zero.(Newton) I have not seen anything that quantifies the eddy current
as being equal in itself as being equal to the missing vector but then science has not found the weak force to prove that it is in singular form and equal to the vector required for equilibrium. If somebody would pick up my theorem that could easily be solved by taking the periphary of the eddy current traveling at the speed of light (frrequency dependant)

Would also like to point ouyt that we have bound electrons as part of
the diamagnetic
material of the radiator the other is an unbound electron or particle
that resides on the surface of the diagmatic
material. It is the charge of this unbound particle we are talking
about when levitated by the eddy current aqnd not the electons that
are bound within the material

G-line, more correctly known as Goubau line, is not practical for use in the HF range. It is generally limited to UHF frequencies and above due to the physical size of the "launchers" which generate a surface wave along the line. For details, see: Geog Goubau, "Surface waves and their Application to Transmission Lines," Journal of Applied Physics, Volume 21, Nov. (1950).

What I believe Hal is talking about was the early practice of using a single wire from the transmitter to connect to an essentially horizontal antenna. Of course that single wire did not behave as a transmission line, but rather became part of the antenna working against ground. In many cases this wire became the actual antenna with the horizontal portion acting as capacitive loading. The resulting antenna pattern is often quite distorted from that expected of the dipole. A good ground is needed on the transmitter, yet problems of RF in the shack are common.

If you do decide to use wood spacers, acrylic urethane varnish applied to dry wood will last the longest and have the best ultraviolet resistance. Shellac, a natural product, actually has a surprisingly good ultraviolet resistance too. While boiling the wood in paraffin wax is authentic, be very careful as Roy, W7EL, points out. The flash point of typical paraffin wax is approximately 380 to 390 F. Use a double boiler with water in the lower boiler to melt the wax keeping it well below the flash temperature. Be very careful as the hot wax causes very bad burns. Work outdoors and keep a fire extinguisher handy. If you have a local source of bamboo, consider using it as it is light and often free.

I have made open wire line using poly(ethylene terephthalate) tensile test bars liberated from the trash where I worked. These PET "dog biscuits" worked well in this application as PET has good resistance to UV and is

extremely tough.

Thanks, Barry on helping to wake up my recollections. I had forgotten that the increasingnes of the spacing of the conductors go into multiple wavelengths, which as you reminded us, is not practical for HF frequencies. But for 2-meters and above, it may be worth a try.
The Bamboo suggestion sounds good, by the way. I used to use 300-ohm twinlead because of the light weight because I wanted the antenna up as high as possible, and more weight made it droop.

I tried this a long time ago and discovered that at least some of the consumer clocks sold here in the U.S. have only a single segment in the tens of hours display digit. That's true of the most recent LED clock I've purchased, so I think it's still common. Don't know how common it is for LCD clocks, but it's possible that only a single segment is connected. I think the problem is that the U.S. is a big enough market that it's cost effective for the manufacturers to make a special version just for it.

Self-setting "atomic" clocks are getting pretty inexpensive these days, so I've got two in my shack beside each other, one set to local and one UTC. The one I use for UTC is made by LaCrosse, and it has a 24 hour display option.

Hi.
I think some Thompson's water seal would be a good substitute for the
boiling paraffin wax. I think the Thompson's is wax dissolved in
kerosene or Diesel. I have been putting two coats on some posts going
into the ground.

Gary,

For VHF contests I usually put the lowest frequency beam on top. After doing some modeling with 4NEC2, the higher you get in terms of wavelengths, the lower your takeoff angle on the radiation.

I also did some modeling to look at the interaction between yagis in a stack. For your set-up, it looks like the 6M yagi should be at the top, the 432 in the middle and the 2M at the bottom.

73, N6FD Erich
Usually QRP Portable in DM15 50, 144, 222, 432, 902, and 1296 MHz

A few years ago, I was caught out of town. Missing the sound of SW/AR,
I purchased a DX-392 by Radio Shack (hey, it was cheap and has a stable
BFO. I have a few cheap radios, just from such "forget-full-ness" ...)

This radio has two clocks, both ONLY operate in 24hr mode. This cheap
radio has served me well ... and of course, one clock is pacific time
and one is UTC/GMT.

However, the wife ONLY thinks in 12hr mode :-) and, ALWAYS corrects the
time, telling it to me in the 12hr format LOL!

Warm regards,
JS

If those ancient OT's heard you state the above, after desiring
materials better than dehydrated wood with hydrocarbons for
preservatives, as their insulators ... well, just suffice it to say,
they'd strike you up the side of the head, HARD! <grin>

Gary,
The 'best' separation distance is as much as you can get. After that, it's more a practical thing, use what you got, do what you can. Will that result in the 'best'/'perfect' situation? Of course not, but it will work in the majority of cases.
A very rough ROT (Rule Of Thumb) is that UHF antennas require less separation than VHF antennas, which require less separation than HF antennas.
- 'Doc

Absolute best distance between antennas is at least 1 mile... in all directions. I'm still working on mine.

> about stacking beams.

Gary,

You may find subscribing to vklogger.com helpful in the upcoming field day.

There is discussion in the associated forums on stacking... search for the work stacking.

The situation is a little different for a field station with low mast height to a home station. Traditional advice might not be best for the low mast scenario.

You didn't mention your power level, or whether you are using a sensitive preamp.

Separation of antennas helps to isolate one transmitter from another receiver, and the harmonic relationship is important in that isolation. For example, your 2m antenna will capture more power from a 70cm transmitter than vice versa, all else equal.

At such low heights, I would be trying to get the 6m antenna as high as possible, BUT, I would separate the 2m and 70cm antennas, especially if running high power. Don't overlook a stack of 2m, 6m, 70cm (top down).

Owen

you know, it took me a while, but i have finally figured out art. art is a politician, and worse than that, he is a democrat. all that talk about equilibrium should have tipped me off earlier! art is all for the weak (force) and wants to get everything into equilibrium by taking away from the strong and giving to the weak. He is also excellent at not answering questions as most of you may have noticed. his slipperyness is only topped by our new president, maybe art has been taking lessons from the big chicago politicians in how not to get pinned down. Just think about it, who else but a politician could go on this long doing nothing but asserting beliefs, even in the face of overwhelming evidence to the contrary. politicians do that all the time, they live on repeating sound bites and bumper sticker slogans for years never saying any more than a dozen words on any particular topic... and the more they get pressed the more they fall back on the same repetitive statements. art does exactly the same thing, always falling back

on 'equilibrium', can't you just picture that as a bumper sticker?!?! maybe
if he repeats it long enough he will get voted into some big science post
and get a big grant, after all, if it gets repeated enough if must be right!

As you know, relativistic effects change the length of seconds. Just after the Big Bang, everything must have been traveling close to the speed of light. (The inflation of the universe is supposed to have happened at much faster than the speed of light.) But what if seconds were simply extremely long due to velocity. As the particles slowed down, seconds got shorter until today we have the shortest second ever to exist - shorter than it was yesterday. Now take today's short second, lay them end to end, and extrapolate the age of the universe. You get a number that is much too large. Conceptually, but not to scale:

BB|-----------------------------------|first second ...
... |--|today's second

What if the first second was actually one trillion of our present-day seconds? Extrapolation would lead to an error of 12 magnitudes in the length of that first second.

Not only are there time effects - there are also space effects. Things are not getting farther away from each other - light-years are getting longer as we speak, i.e. space itself is expanding, i.e. the standard meter in the National Bureau of Standards is getting longer as we speak.

What happens when me measure the light frequency of distant galaxies while, during the travel of that light, light-years were getting longer and seconds were getting shorter? Hint: same thing that happens when the time base knob on an oscilloscope gets loose and slips. (That actually happened to me and the result was an epiphany about space/time.)

I recall an article that HROs were also used but can't find much. Does anyone know if National made a tone decoder, I'm using RCAs nomenclature because that's were I got most of my info. What were some other names for the device, that RCA called a tone decoder?

Art Unwin wrote:
"I am still of the belief that on a fractional wave antenna the current travels on both the outside and the inside of the radiator."

That`s so at DC but not at HF.

HF only travels on the outside layer of a conductor as more current-opposing flux lines encircle the conductor`s center than encircle the conductor`s surface or outer layer. See Fig. 2-10 on page 22 of Terman`s 1955 opus.

Art also is confused about current distribution on resonant antennas of various lengths. Terman can help there too. On page 866 Terman wrote:
"The current distribution as observed in such a resonant wire (1/2-wave open at both ends) serving as an antenna ordinarily approximates very closely the distribution that would be obtained on the assumption of zero loss. provided the wire length does not exceed 8 to 10 wavelengths. The current distribution, accordingly has the character illustrated in Fig. 23-3."
Also on page 866:
"----to a first approximation the current distribution can be taken as that for a line with zero losses; it then has the characteristics discussed in Sec.4-5."

Page 91, Fig. 4-3 shows the vectors (phasors) E1 & E2 at an open-circuited load as happens at the antenna tips, Conduction current ends at the conductor tip. Current interruption collapses the magnetic field and induces an opposite current causing a zero sum current at the tip, but the induced voltage is of the same polarity as the incident votage making a voltage double at the antenna tip. Energy is conserved.

Best regards, Richard Harrison, KB5WZI

Howard-

I built a clock from Radio Shack plans and parts back in the 1970s.
That chip had the 24 hour option, but used the same pin to change from
60 Hz to 50 Hz! I got around that by using an SN7410 to convert 60 Hz
to 50 Hz.

Could you give a similar description only this time make it a 5/8
wavelength antenna?

I guess you mean "Two phyicists". Problem is they are not physicis:
No degrees listed, no university affiliation, no publishing list, no
professional society affiliation, papers not published in scholarly
journals therefore no peer review. Probably more that I have
missed.

Even where the three papers were presented (PIRT 2006)
looks like it would not stand up to too much scrutiny. At
that point I lost interest.

73,

Frank

Hmmm, that is sad, so very sad ...

In other words, your logic, education and reasoning powers make you highly dependent upon "rubber stamps", and, unable to think for yourself, reason for yourself, use high mental capacities--you are stuck with dependance on a "USDA stamp" telling you the "meat" of the matter is fit for you consumption?

You, certainly, must be the product of this generation ... this is so unfortunate, when I was in college they taught us "how to reason", and "how to research"--NOT WHAT TO THINK, HOW TO THINK or IF IT WAS OK TO THINK ... I guess just like cheap crud made in china ... so has gone the education given to this new generation ... perhaps you could complain to the college who has turned out this "inferior merchandise?"

... sad, so very sad ... :-(Best of luck, may you find better on the path yet left before you ...

Regards,
JS

Hey Guys
I made an error when I called the RCA device that selects the best Rx a
Tone Decoder, it's called a Tone Keyer. It selects the strongest of 3
HF Rx signals and amplifies it. What did the other HF diversity makers
call Tone Keyer.
I know about CTCSS but its unrelated to my query.
Thanks
Hank

My A4S is acting wierd and I cannot figure it out.

20 meters its got great SWR. 15 is so so but tunable with a tuner
and stays relatively flat.

However 10 meters, the SWR stinks and I can try to tune it with a tuner
but then it goes out again. And I can swing the beam and hear the
Noise pick up and go down with the turning of the beam and when it stops
it wiggles a bit and the SWR changes. The tube and trap connections all
see secure.

Do I have a bad trap or ?????

Scotty W7PSK

Do you have the water drain holes pointing down?

Art Unwin wrote:
"Could you give a similar description only this time make it a 5/8 wavelength antenna."

My previous resume` regarded current distribution on a 1/2-wave standing-wave antenna.

A 1/2-wave antenna is resonant, that is it has no reactance, and it is open-circuited at both ends. Its feed point is in its center, at its high-current point, and it is a pure resistance.

The 5/8 wavelength antenna consists of a 1/2 wavelength section of radiation resistance but no reactance plus a 1/8 wavelength section of small radiation resistance and a large capacitive reactance. To receive maximum energy, the capacitive reactance must be compensated. A unity power factor is desirable.

As with the 1/2-wave antenna, current distribution in the 5/8-wave antenna is controlled by its open-circuited ends. On page 187 of the 3rd edition of Kraus` "Antennas" he says:
"A sinusoidal current distribution may be regarded as the standing wave produced by two uniform (unattenuated) traveling waves of equal amplitude moving in opposite directions along the antenna."

We know there`s radiation and loss as the current travels to and fro between the open-circuited ends of the antenna, but if unattenuated is good nough for most purposes for Kraus, it is good enough for me.

Best regards, Richard Harrison, KB5WZI

First thought is a 'not good' electrical connection somewhere. A 'joint' may seem secure but be a bad electrical connection. No idea if you have a bad trap. Making sure that they are not filled with water or whatever else would be a good idea (drain holes pointed down??). I would think that having to use a tuner means that maybe the antenna isn't adjusted correctly? If you can get it to a point where you can do all that checking of joints, etc, why not just take it apart, clean it, and put it back? (Easy for me to suggest, I ain't the one doing it, right? ;))

"We know that..........." !!!!!!! hmmmm

I don't know who "we" is but for one I don't know
Could you explain who "we" is and on what authority or explanation
has "we": got for such an implausable statement?
I do thank you for responding. Oh what a web we weave when we try....

May be this is why scientists have not yet been able to rationalize
radiation
and we are just left with theories with holes as in cheese.
Industry shows us not just talk about it they show us every day what
happens to a particle
on their conveyor. They even let you show the particle levitated and
revolving.
Industry also shows you that eddy currents occur in a closed loop
circuit
and one must see that the combination of the alternating current flow
and the resulting eddy current can
levitate a particle. They don't just talk about it they can
demonstrate it.
This is much more plausable and reproduceable than wireing a house
with an open circuit to plug into.
Also the old books that you read on both argue that a fractional
wavelength is represented by a series circuit that is not open!
They also say that a full wave antenna is represented by a parallel or
tank circuit and again the circuit is not open!
No wonder radiation has not been explained fully when so many
paradoxes are present. Oh and if my house is wired as an open circuit
asit is time related why on earth would one need fuses and where would
they put them if it is an open circuit?
The idea of two currents opposing each other on the same surface of an
open circuit where the eddy currents is thus cancelled
by revolving in opposite directions and the same thing going for the
time varying current tells me you have discovered the "big bang"

by not placing a fuse in an open circuit.
Kraus was not perfect otherwise he would have improved on his thinking
during his life time
by studying radiation and it's creation.

Regards
Art

Richard:

I certainly don't want to engage in a large argument.

Rather, I would just venture an opinion directly related to my real world construction experiences, and the results from the same:

If there are notable gains from constructing a 5/8 wave antenna, as opposed to a 1/2 wave--I have NOT seen them.

It all looks good in EZNEC and/or mmana-gal (or, "on paper"), however, in real world s-meter/signal-reports, "it" does not.

Perhaps I have experienced a anomaly(s?)

Or, put simply, the extra "hassle" in dealing with these extended lengths is simply "not worth it!"

Regards,
JS

art is fun! he gives me something to laugh at when the wx is bad.

usually oe does quote properly, but something is different about art's
posts, they must be in a format that oe doesn't like so it won't
automatically indent and quote them.

David
There is something odd about that post. I have not been dabbling in
other newsgroups other than a short stint

on Eham. I have not stated that I get more resposes than anybody else on the net. So I really don't know where he is coming from
I have no problem in people killing my file as that would leave people who want to discuss antennas instead
of staying purely for insults and argueing reasons. Perhaps he is one of the kb9.... group that are intent on destroying newsgroups
before somebody divulges where he lives so that people can decide how to react. Maybe when the table turns on him he will ponder
if his behaviour justified the response he gets!

Now back to antennas, how can one determine if current does or does not flow in the centre of a conductor? by separating It was the basis of equilibrium of a radiator
that allowed the use of Newtrons law to determine that if a charge does not move in sync with the current then no current can be flowing thru the center.
Nobody used Newtons laws in the case of a fractional wavelength antenna.
but of a bound electron breaking away from the orbits of the material. This thinking says that a antenna will dissapate over time so we must consider the possibility of an unbound electron at rest upon the surface which brings us back to the Newton domain Is it beyond the sensabilities to see it as an action and a reacgtion between the settlement of particles on a surface and the reaction to this action by the application of current which provides a reactionary field. This idea of waves moving along with the current flow and various other ideas put forward by the likes of book authors seems to be a never ending attempt to provide substanced to a long ago thought out bad theory which would be disrupted if current was observed to flow in the centre of a radiator

its only an art to art its a science to everyone else. art paints his
antennas with magical mystery jumping diamagnetic neutrinos that levitate in
the breeze. sounds like paintings like the melted watch and distorted
perceptions to me.

The theory is well tested and good.

Authors often write books to inform. They are paid for their efforts.

Skin effect is a fact of agreement among the scientific community. A proof is readily at hand. Coaxial cable keeps what`s inside in and what`s outside out.

The best exposition of "skin effect" that I know of is found in chapter 27 of "Radio-Electronic Transmission Fundamentals" by B. Whitfield Griffith. The 1st edition was published in 1962. It was republished by Scitech in 2006. Art would enjoy and benefit from all 638 pages.

No David, I am trying to lead people away from the idea of break away elements from the radiator
substance itself. We all recognise that the rotation of the Sun has a pivitable place in radiation.
It is also estimated that there are billions of particles per cubic meter here on Earth which came from the Sun.
So what is so wrong in looking for a connection between these particles and radiatiation? After all we are aware that they will come to rest on a material that will not apply a bond to these particles such as a diagmatic material which radiators are made of?
We also know that these particles in flight must have a straight line projection that exceeds the gravitational pull and possibly this is the weak force which is acknoweledged in the science community! Yet we hang on to the idea that current cannot flow in the center of a fractional wavelkength radiator
purely on similar speculation since it has never been observed or proven. It just isn't a lot of sense and the ARRL could not care less relying on a cycle of informing new hams how to solder a connector on coax.
Good grief
Regards
Art

Richard I have made my thoughts known on radiation as well as the path
I followed
that brought me to where I am. In the past 100 years or more science
has not come to a consensus as to what energy is.
Einstein seached all his life for the weak force which he considered a
major part of radiatiation which leads to a Unified theory.
Today there is not one book thaat can provide a satisfactory answer as
to how radiattion is created.
What I am saying that there are to many theories that are being tagged
upon one another leading to an incorrect trail upon which books are
being printed
for a individual generation. So I proposed to myself a retreat from
the books and go back to Maxwells laws plus those of the masters that
provided the information to him and then with an open mind looked at
it with the 21st century in mind and the information garnered by
observation as opposed to theory.
Present day science is all a buzz about Neutrinos, CERN and the Sun
which is in a continually burning state creating partly burnt
constituents.
Gauss has a law dealing with particles and I have an interest in ham

radio. It is therefore natuaral to me that in light of present day observances
Einstein may well have been correct even tho not aware of discoveries found after his death. Thus my concentration was on outside particles and not the wave style theorem and thus eventually arrived at the weak force phenomina which is in use in many ways on Earyth which can also be subcribed to radiation. But saying is not enough so I have used Maxwellian computor programs to design these antennas with good results all of which are bound
to the edict of equilibrium which all the past masters adhered to. Einstein was not privy to a lot of things that I used on my jorney but many hams do
and can easily confirm my findings which are observables not dreams that support Maxwell. Books cannot and do not provide an actual journey that provides a trail without gaps for the generation of radiation. I have by starting the trail at the beginning with present day science in mind and not pursuing the mode of academics who seek favor by piggy backing theories of those who have received award thus shutting out a;ll other aproaches.
Yes my thinking is known and yes I think for myself with no formal attachment to the books upon which my education started where it is incumbent on graduates to continue to hone and secure futher information for the next generation rather than the sole pursuit of personal wealth.
Best regards
Art Unwin KB9MZ.....xg (uk)

Oh My Richard, are you suggesting, but frightened to suggest, that
skin effect is something other than the
swirling eddy current and its negative magnetic effect on the main
magnetic field provided by the applied varying current?
Forget the constant lines of books that you have brought in to the
discussion, what exactly do you think that provides the resistive
action of
skin effect using your own 19 century smarts? On the other hand, if
you have no thoughts of your own then by all means steal an idea from
the Witfield book and share it with all of us. The fact that this old
book is being republished by the publisher is to obtain money and
should not be seen of verification of its contents. Neither should you
accept everything you read without challenge in the absence of any of
your own thinking obtained some 50 years ago.
when you had to listen to a professor so you obtain conformity with
him when the examination paper is judged by him no less?

Wouldn`t anyone like to be aware of all the discoveries made before his death?

Einstein said something like: "Keep it simple, but not too simple!"

Scientists have in many instances followed Einstein`s advice and reduced things to simplest terms. Maxwell`s equations as simplified and explained by Heaviside have been used to successfully predict EM behavior for a century. They give the answers needed so there has been no great search for a replacement.

The research at CERN on colliding beams is more likely of interest to those working with ionizing radiation than to those working with the nonionizing type we use in radio telecommunications.

There is and was agreement among many with Kraus when he wrote on page 37 of the 3rd edition of "Antennas":
"Although a charge moving with uniform velocity along a straight conductor does not radiate, a charge moving back and forth in simple harmonic motion along the conductor is subject to acceleration (and deceleration) and radiates."

An interesting view of the mechanism of radiation is given by B. Whitfield Griffith, Jr. on page 315 of "Radio-Electronic Transmission Fundamentals".

Power handling and efficiency increase as the frequency decreases; a
solid center conductor doesn't help at LF either.

I`ve had both editions. They are identical in content (no corrections). Terman says essentially the same things about "skin effect". Griffith`s examples and drawings are more extensive.

Charges are moved to the surface by reduced inductive opposition there.

Imagine a wire made of many concentric layers. Each layer`s current produces inductive opposition. This is generated by the current that layer carries. The inner layer is encircled by all the lines of all the layers while the exterior layer is encircled by only the lines generated by its current and none from the lines generated by the current in the layers under it. Thus, there is little inductive opposition to current on the surface of the wires.

Thank you for that Richard. I suspected that such an old book as with
Terman
would not be abreast of the present times and still hanging on to
ideas that are
not in sync with the present day thinking. You surely must know that
a time varying field
upon a diamagnetic material also creates what is known as the Foucault
or eddy current field.
Present day non destructive material testing duplicate this method to
provide a means of looking for a crack or fissure in
materials often after heat treatment or welding. On a unimpared
surface the eddy current swirls
in a closed circuit form on the surface as a result of a applied time
varying current. Relly a reaction in terms of Newtons law.
If there is a crack or fissure in the surface the closed circuit of
the eddy current is broken and it is this that todays inspection
equipment relies upon.
Ofcourse this created magnetic field is in opposition to the applied
magnetic field and this opposition is called a skin effect.
It is called a skin effect because like the aplied current the eddy

current flows on the surface of a conductor and is limited in
penetration.
Ofcourse when this rotating magnetic field is combined with the main
magnetic field its rotary action makes short use of particles that
abide on the surface
where it supplies spin to the particle while excellarating the
particle in opposition to gravity. Ofcourse Richard your term in the
military taught you that a rifle has as groove that curls inside the
barrel which you know is to provide a spin to the bullet so that it
does not wobble end over end and thus lose its accuracy. The particles
by the way are sub atomic and so small that they can pass thru
retaining threads as it were on most materials so its mass and energy
content is quite small such that it will bounce off of rthe shields
surrounding our earth but not so much that it looses its resistance to
gravity before it finds a suitable radiature of resonance that it can
rest upon according to the direction aimed by the transmitter. It will
not deviate from this course if the receiving antenna is not directed
in substantially the same direction. Since there are a lot of these
particles around on Earth there is a scramble for a suitable place to
rest so any vacancy is immediately occupied such that radiation is a
huge lot of levitated particles. Fortunately the Sun keeps on burning
pushing particles away from its own gravitational field otherwise the
11 year cycle would become a century old plus cycle and we would look
for another hobby.Another thing Richard these particles are extremely
small so we will not finish up knee deep. On top of that they also
decay because of diminishing
nuclear content which we see the results of when there is a sun burst
and the clustered particles get into our power system and overloads
it.

And for the second thing... I happen to have problems with
portraying a dummy load on a stick as the answer to all things
of a radiating nature.
I've seen his antenna, and I know how it was built.
It's a dummy load on a stick.
See for yourself. Don't just take my word for it.
http://www.k8gu.com/webpost/unwin-antenna.jpg
Note that this antenna is for 160m use.
My MW receiving loop would likely out radiate that thing.
If I used my mobile antenna, it would get ugly.
All his antenna is, is a helical whip, with contra wound
windings to make it even more lossy than if it were wound
in a normal military manner.
The extra "coil" on top is basically useless, and only adds
a small bit more inductance to the antenna. Maybe enough
to scoot down the band a few kc's.. :/
He says it needs no ground plane, but being it is a vertical,
it sure as heck does, if reducing ground loss is an issue.
Of course, if one is willing to ignore massive coil loss, it's
no large stretch to assume he has no problem ignoring
ground losses either.
What is hilarious to most, is that he uses bafflegab mumbo
jumbo to try to explain the workings of an antenna that is
not only prior art I'm sure, but also a very perverted version
at that. I compared his antenna to a MW loopstick used for
receive purposes only.
Look at the picture and tell me your analysis.
You can apply plain old known vertical antenna technology
and come up with a pretty accurate assessment of the
efficiency of his antenna.
Mumbo jumbo is not required for this task.
Fairy tales won't cut it either. Nor neutrinos, the weak
force, or the shoe size of Captain Kirk.
Maybe this will shed some light on my persistent
skepticism of his illustrious, but stinky design.

The antenna you are referring to is an antenna that does not transmit but does receive. This being contrary to accepted amateur lore that all antennas are reciprocal
It was given to a future doctorate from the University of Illinois a University who as a whole actively disses any
ideas from outside the academic field So I gave him a antenna that he expected to get.
Prior to this "gift" which I also related to this group in detail. I found out that when you superimpose a helix over a helix in contra wound form the
eddy current magnetic fields cancelled each other such that the particles were not levitatedwhich is required for transmissionthe latter which
From this I learned that a radiator can only be of a varied shape and in equilibrium as long as there was no interference
to distributed loads. Removing this inter action from the radiator allowed levitatiuon of the particles such that it CAN transmit as well as recieve which is not determined by a levitation action. Try it for your self and do not compare a resistance with out distributed inductance and capacitance with multi windings of distributed capacitance and inductance. I know that you never completed high school but there is no reason to stop reading technical books
just because you were thrown out which is foolhardy not vengance. The photo in question was displayed solely as a prop by those who wanted to diss my theory which is exactly why I suspect that you are using it now. and good enough reason for me to supply a antenna that I did.
areana. Now any antenna can apply an overlapping helix to any antenna computor program including the very limited EZNEC program to determine the results for themselves, it is not essential to have a optimizer so there is no need to imitate a talking head in dissing what I am sharing.
Art

Duhhhh... I guess it never occurred to you that the overall signal
and noise levels at that frequency are so high as to let nearly any
length of metal act as a decent antenna.
I'm sure the theory of reciprocal antenna operation was not
broken in your case. I'm sure that the level you saw was about
20-30 db down from the level you would have had from a 1/2 wave
dipole. But.. being as you seem to refuse a reference antenna to
compare to, you would never realize this.
Of course, a loss of 20-30 db is not enough to kill you at
that frequency. My un-amplified MW loops are a prime
example of that fact.
Your antenna should be less efficient than my 5 turn loop,
but still should be usable as a receive antenna.
Art, for someone with such a self proclaimed vast education,
you are as thick as a brick.
Note that this was a popular song from a fairly popular English
band back in the last century.

Rest of rambling jibber jabber mumbo jumbo deleted to help
preserve sanity among the various readers.

So you think I should succumb to those who diss me without foundation
and give then
a proper antenna? Not me, I say gottcha.! And as far as your assertion
that all verticals must have a ground plain
that is exactly what I would expect of you. Read books instead of
looking for vengance on who stayed in school.
Somebody on this group offered you a wager of $1000 or was it more, to
refute your assetrtion that I didn't have such an antenna.
He stated he would supply the wager up front and I stated I would go
along and supply the antenna. What did you do?
You squeeled and groaned and got lost for a while and revealed
yourself as a talking head. I am done with you. I am not going to
respond in like nastiness but just avoid contact

Yes, I think you should. I have yet to see a model, photo, prototype, description, patent, test results, or other physical manifestation of your antenna. I would really like to see an antenna design based on equilibrium, that ignores skin effect by having current flow in the middle of a conductor, and that is any way superior to conventional designs. I'm quite open to radical new theories and implementations. Hopefully, it will be built from something more common that unobtainium.

We have quite a solid foundation to "diss" your theories.

>Not me, I say gottcha.! And as far as your assertion
> that all verticals must have a ground plain
> that is exactly what I would expect of you. Read books instead of
> looking for vengance on who stayed in school.

Typical Art response. I've read the books, and I've used the
real antennas. Have you? Oh yea, you dismiss everything you
read in books. :/
Anyone with a clue knows that even "complete" verticals such
as a 1/2 wave can still suffer the effects of ground loss.
The loss is not quite as large as with the 1/4 wave monopole
due to the change in current distribution, but it is still there.
Why do you think that AM broadcasters that use 1/2 wave
verticals, also use a radial set of 1/2 wave radials?
For their health? To spend money that otherwise could be spent
on donuts for the fat slob at the mike? To be stylish?
Cuz Uncle Joe Bob is in the copper industry and needs more
work?
Good grief.. :/
The 5/8 radiator really should have an opposite 5/8 radiator,
rather than a ground plane. The usual 1/4 wave radial set for
an elevated ground plane is a poor choice.
But the problem in that case is not so much ground loss,
as it is perversion of the pattern due to using what I consider
a perverted unsymmetrical antenna.
This is why some people whine that their 5/8's antennas don't
live up to their expectations.
But if a 5/8 radiator is ground mounted, it too requires a radial
set to reduce ground losses. Go call WBAP and ask the
engineer if they have any wire in the ground.
This also applies to elevated dual 5/8 verticals if they are low
to the ground vs wavelength.

No one did any such thing that I'm aware of. Show me the google
archives. You are either totally full of crap, or must have me
confused with someone else. "that actually gives a @#$%" :/
Why would I care if you have an antenna or not?
You need to get a grip on reality.
I could give a rats heiney, and most certainly would not bother to
make any wager over you having one or not.
The reason I suspect this, is #1, I don't gamble. At all.
Even at Vegas. I don't even play the lottery.

>I am done with you.

You can bet I'm not done with you though if you persist with
the usual mumbo jumbo jibber jabber.
I consider it my moral duty to expose all the stinky I run across.
So go ahead, make my day.

Jeff I tried to share everything over the years with fellow hams but
all I got were insults
I have applied for patent an as wilh the later forms as I learn more
they eventually will come to light. I also have a page which
is now empty as after a deluge of insults so
I took it off the web.Hams got angry. It seems that hams feel that
they have the right
to everything regarding antennas and they did get all the information
I have but the dissing goes
on as they are not willing to think for themselves. Should I go hell
bent on supplying samples to the ham community
when they refuse to recognise the veracity of any thing I say?
Ofcourse not and I thus care not for similar talk from you.
The group cannot prevent the disclosure and the "me to": attitude will
come back when all is revealed, Until that time I will not reward
those who automatically diss everything I share in the hope that they
will shame me into giving them a sample.
I am happy that they continue to post despite the lack of responses as
their practice of using free speech allows us to measure who and what
they are so that we do not involve ourselves with the like oif them
and KB9......all of which seem to be of the same type of miscreants.
I received a posting today from the likes of KB9... which all can read

for themselves, he will not get anymore responses from me as I do not wish to be assdociated with such a group which judging by other lack of postings is the attitude of most of this group.
Have a happy day
Art Unwin KB9MZ...xg...(UK)

I love Einstein, but then, I have met few Germans I didn't like ...

However, gravity serves a prime example of what you suggest, here. We know nothing about it, but a lot about its' affects and effects; we have many formulas to tell us about those and a few theories to tell us what it (gravity) actually is. So, I doubt it surprises anyone that we stand at, almost, this exact situation with EM.

However, to lift the blanket and peer upon the true substance and nature of these things would take us to a whole 'nother level of possibilities in their uses ...

So, if you argument is going to become, "We already know enough of these things, let us go no further"; well, some just may follow you--some not ... personally, I'd "druther" not ...

Warm regards,
JS

If a time varying current is flowing thru the center of a conductor
it cannot, I repeat cannot produce either a field from the applied
current
or provide an eddy current. The only loss it experiences is a copper
loss
which is minimal and I "beieve" such resistences are limited to
certain value by the FCC;(6 ohms) for broadcast stations
It can be seen then that the radiation from a radiator not in
equilibrium is relatively efficient with respect to applied power
even tho it is not radiating from the center of the radiator. If you
know of an experiment that was devised to show that no current flow in
the center I would apreciate a heads up. But I would also remind you
that it was Newtons law with respect to equilibrium that led
scientists to declare that current travels on the outside without the
need for furthur experiment.
Art

I'm really not interested in reading any more assertions, allegations,
accusations, theories, analysis, or repetitions of your previous
postings. Please re-read what I wrote. I would like to see a model,
photo, prototype, description, patent, test results, or other
physical manifestation of your antenna based on equilibrium and/or
whatever you're claiming about conduction through the center of a
conductor. Show me a *REAL* antenna that works according to your
rather unique principles. I'm open to proof and demonstration, but
not to furthur allegations and claims.

Jeff you are not telling the truth again it is becoming a habit of
yours .
Sometime ago you asked me to confide with you some facts about the
antenna as you were of open mind
I then gave you the Gaussian extension information which you could
then compare with Maxwells laws mathematics or alternatively
place it in a Pointings circle. You immediately came back and dissed
the aproach without mathematical evidence so you could join others and
throw stones. I like to keep to the truth especially as I get older.
Apparently you are not afraid to show your true colours when your lies
are detected.
Frankly I can't see me going out of my way to provide a demonstration
thus leaving it to real open minded hams to pursue. Apparently a lot
of hams do not
want to know the truth. As Richard has stated we already have an
antenna so there is no need for another one, seems like he is not
alone in that thinking
when one is not proficient enough to do the math

The funny part is trying to figure out who is the commedian and who is
the straight man. Sometimes I think Art is just someone from the CB
groups bashing y'all around. There is just too much consistency to his
insanity.

I ask for a real antenna, and you call me a liar. Somehow, the
connection is difficult for me to establish. Even if I were a liar,
how does that affect your inability to produce a working antenna?

>Sometime ago you asked me to confide with you some facts about the
>antenna as you were of open mind

I don't recall any such request. Please not that you are making the
claims and allegations. I'm merely suspicious and curious if there is
anything substantial behind your claims. I do have an open mind and
am willing to accept some rather odd theories as possible. I've made
some rather bad mistakes in the past by pre-judging various
technologies. For example, at first glance, I declared MIMO to be
impossible. Such mistakes make me more tolerant of your theories, but
only to a point. I've been reading some of your postings for several
months, and have yet to see a real antenna.

I am rather impressed that you would go through the effort of applying
for a patent on a random array of elements. If granted, it should
give you the rights to most ham radio antennas that were assembled
without a clue or calculation.

>I then gave you the Gaussian extension information which you could
>then compare with Maxwells laws mathematics or alternatively
>place it in a Pointings circle.

There is no Pointing circle. It's a Poynting Vector:
<http://en.wikipedia.org/wiki/Poynting_vector>

>You immediately came back and dissed
>the aproach without mathematical evidence so you could join others and
>throw stones.

It's not my position to supply equations for your theories. If you've
found some mathematical extension, principle, or approach that is
based on Gauss, Maxwell, Heaviside, or Poynting, it's your
responsibility to supply those equations. I haven't read all your
postings, so it's conceivable I've missed them. Could you provide a
searchable reference to those equations so I can decide for myself if
they make any sense?

>I like to keep to the truth especially as I get older.

Personally, I find it easier to lie as I get older. Credibility and
authority tend to improve with age.

>Apparently you are not afraid to show your true colours when your lies
>are detected.

That's the 2nd time you've accused me of lying. I don't care. I'm
only interested in your theories on antennas. If you find it
necessary to divert your production of suitable evidence of your
antenna, I'll gladly cooperate by admitting to lying at all times,
about all things, and for any reason, simply so that you do not feel
compelled to avoid the question. Where's your antenna design?

>Frankly I can't see me going out of my way to provide a demonstration
>thus leaving it to real open minded hams to pursue.

Frankly, that the only thing I'm interested in seeing. You've done
everything EXCEPT provide such a demonstration.

>Apparently a lot
>of hams do not
>want to know the truth.

Would my lies suffice as a reasonable substitute? It really doesn't
matter. The only thing that is important is whether a real antenna
can be built, analyzed, and demonstrated.

You can look in the archives for yourself to remind you of that incident, you have not been on this newsgroup for any length of time so it should be easy
As for requiring a demonstration I have other patents on antennas which are purely for my personal record I did not hawk it around to vendors but I did share it with hams. When at work samples are required and the company attorney vets the application, as an individual I can and do put down what is required to back up claims leaving it to the examiner to provide suggestions of same such that it has a tad of credability if challenged. I would add that I had to provide a sample of one antenna to the PTO before a application award was accepted. One person offered to provide the majority share of a company if I would assist in a start up for one of my antennas. I refused because my intent was to enjoy my retirement without the need of obtaining more money when I have enough. Now I am doing a similar thing with a different antenna that has broader academic appeal beyond antennas and yes I paid the money to the PTO purely for my records, and there is more to be revealed as per what I have disclosed previously to this group.and nothing more.
I am what I am and do as I say and share it with all so they may discard if they wish as it is my personal .satisfaction that I search for,. If you or anybody else are offended I have no problem if you block my posts which would then remove the need for offending comments back and forth

Oh? I have to do the searching to prove YOUR accusations? Forgive my
laziness but I'm a bit busy tonite defrosting the fridge (hammer and
chisel required).

>As for requiring a demonstration I have other patents on antennas
>which are purely for my personal record I did not hawk it around to
>vendors but I did share it with hams.

These?

Constant impedance matching system
<http://www.google.com/patents?id=hCMpAAAAEBAJ&dq=5,790,081>

Variable capacitance antenna for multiband reception and transmission
<http://www.google.com/patents?id=GEsbAAAAEBAJ&dq=5,625,367>

Push button arranged for mounting to a panel
<http://www.google.com/patents?id=qaY3AAAAEBAJ>

Push button assembly
<http://www.google.com/patents?id=YF0tAAAAEBAJ>

Very nice. I like the motorized matching or tuning capacitor inside
the yagi boom idea.

>and there is more to be revealed as per what I have disclosed
>previously to this group.and nothing more.

I'm patient. Let me know when you have something substantial to
disclose.

>I am what I am and do as I say and share it with all so they may
>discard if they wish as it is my personal .satisfaction that I search
>for,.

It's your right to do with your designs as you please. I asked you to
demonstrate one that uses equilibrium and/or conduction in the center
of a conductor. I guess that's not going to happen.

>If you or anybody else are offended I have no problem if you
>block my posts which would then remove the need for offending comments
>back and forth

No problem. However, other than you calling me a liar twice (without direct substantiation), I would be interested in which of my comments offended you? I expend some effort in trying to be technically accurate and non-offensive. Apparently, I've failed and would like to know precisely where.

The last time that I built an antenna I used the formula to get the
appropriate length then I had to adjust it to obtain the optimal
readings for the frequency I was using.

Ever seen the coax used on TV transmission lines? In rough numbers is is
a pipe about 6" in diameter with another pipe about 1" in diameter held
centered inside the larger one by spacers.

Did "the formula" take into account any insulation, conductor resistivity,
conductor diameter, height above ground, characteristics of the ground,
and objects in the near field including supports?

If not, what is your point?

Source record: 20120

Just wondering what people's opinion is on this... I'm trying to decrease the overall mounted size of a jpole design. In the past I've always tried to keep the bottom 1/4 wave stub section well above the mast top. Just for the heck of it, I started testing with the stub below the top of the mast (mast blocking the bottom 1/4 wave stub). The antenna is still electrically isolated from the mast of course... but what I found is that I was able to mount the antenna to the mast and have it go up the first 1/4 wave stub part of the antenna at least 2/3 of the way, before there was any SWR problem at all. In fact, there was virtually no difference in the SWR doing that, as compared with having the very bottom of the antenna well above the mast top. Can anybody think of any other adverse effect in doing this? On a fairly low band it reduces the overall size of the antenna significantly, so it's definitely an advantage to mount it lower, assuming there's no adverse effect on the performance. The SWR doesn't seem to change at all until you start getting the top of the mast up near the actual 1/2 wave portion of the antenna.

Thanks for any help,

There may be a problem with mounting hardware detuning the stub.

The rule is that a conductive support needs to be kept
a few diameters away from the spacing of the non-radiating
stub. If that condition is met, it should be OK.

The point is that those items are not part of "Antenna Theory: The Science" but are a large part of "Antenna theory: The Art". Art has been talking as if they are one and the same.

Something you could answer if you can. I am planning to install a dipole antenna in NVIS configuration adjacent to a mobile home type structure. The wire will be within about 10 to 15 feet of the metal covered structure. How much will the metal warp the radiation pattern of the antenna. It will be in the 75 to 60 meter bands.

"L.S. 03.05-08.Jyrki Niittymaa.Ydinvoiman�k�kanta tulevaisuuteen on, ett� jo olemassaolevistakin yksik�ist� tulee luopua puhumattakin uusien rakentamissuunnitelmasuunnitelmista. Mielipidekirjoituksissa ja tekstipalstoilla tuodaan usein esille, ett� Suomi olisi yksin��n ydinvoimahuumamaa.Vastustajat korostaa laitosten vaarallisuutta tavalla, jolla viitataan katastrofaalisiin seurauksiin mittaamattomaksi ajaksi. IAEA:n tilastojen mukaan kaikkiaan ydinvoimaloita on j�ljell� EN�� 439kpl! (Tilanne tarkoittaa sit�, ett� aiempi ydinvoiman 2% maailman energiantuotanto-osuus on rajussa laskussa, koska jopa ydinvoimaloitten KOKONAISM��R� on kovassa pudotuksessa muun energiantuotannon noustessa vuosittain maailmalla taustassa useita prosentteja. Siksi esim. Kiina 5-kertaistaa satsaustaan suhteessa nyanssiseen ydinvoimaansa jopa viimewvuotisia suunitelmiaan enemm�n. Syyn� on kuulema se, ettei ydinvoima sovi energiakalliina ja hitaana s��t�kyvytt�m�n� perustarpeisiin, ja kansalaiset vierastavat ydinvoimaa nyttemmin my�s siel�! Siksi Niittymaa jatkaa tiet�ess��n, ett� mm. t�n� vuona maailman valloittavat p��st�tt�m�t , piiputtomat voimalat alkavat dominoimaan maailman energiamarkkinoita , kuten TVO:n mm. Nikula ja Luhta kommentoivat taannoisessa YVA-kokouksessaan, Jyrki jatkaa:)

Korostettakoon taas kerran t�ss�kin yhteydess�, ett� muita tuotantomuotoja, erityisesti uusiutuvia, ei pid� v�heksy�, tai j�tt�� k�ytt�m�tt�! Viimek�dess� mm. k�ytetyn polttoaineen loppusijoittaminen tuntuu pelottavimmalta uhalta kauhukuvineen satojen vuosituhansien p��h�n!" Hei siis VAUTSI, kaveri alkanee heijastella syit� siihen miksi jopa SDP on luopumassa ydinhysteriastaan!)

*Koska maailman ydinvoimaloita tunutaan alati vaan purkavan enemm�n ydinvoimaloita, kuin hidas ja ponneton rakentaminen on vuosikymmenten odottelussa tuottanut. Juuri kuten IAEA ennakoi tapahtuvan energiapositiivisen uraanintuotannon loputtua -07. Mutta on t�ss� toki my�s muita motiiveja. Kuten monet muistavat TVO k�ytt�� nyky��n JOKAISEEN ydinvoimalaan sukupuuttoon kuolevan valaan/vuosi. T�m� n�kyy n�iss� mm. MTC-palojen rasvank�yt�iss� ja vastaavissa sitten n�in, kun kampamaneettikasvattamot tyhjent�v�t valailta my�s kiihtyv�sti ruuat:"Norjalaiset valaanpyyt�j�t ovat saaneet saaliikseen viisi lahtivalasta. Kertoi norjalaislehti perjantaina. Valaanpyyntikausi on on ollut k�ynniss� jo runsaan kuukauden, mutta pyynti� on haitannut huono s�� ja jatkuvasti kohoavat polttoainekustannukset. Norjan itselleen asettamat valaanpyyntikiinti�t t�lle vuodelle on reilut 1000 lahtivalasta. Kiinti� oli saman suuruinen my�s viime vuona. Norja irtisanoutui kansainv�lisest� valaanpyyntikiellosta vuonna 1993 v�itt�en, ett� valaanpyynti on v�ltt�m�t�nt� lahtivalaskantojen pit�miseksi sellaisena, ettei haittaa kalastusta. Lahtivalaat kasvavat 11-metrisiksi ja painavat kahdeksan

tonnia."

*Ja tosiaan n�ill� tappokinti�ill��n juuri ja juuri hoidetaan alati katoavaa ydinperint�� ja hiukan rasvaa riitt�� my�s varastok�ytt��n.

Science is fully accounting for all variables and their effects giving
you exact answers.

Art is experience and rules of thumb that get you close enough.

I can't but it should be easy enough to model in EZNEC.

Alan arvostuksesta kertoo varsin suoraan se miten alan ammattity�v�est�
suhtautuu tekemiseens�. Siit� voidaan ottaa esimerkkej� laajasti.
Ammattilaiset haluavat usein my�s j�lkikasvustaan ty�ns� jatkajia.
Yritysmaailma on pullollaan ty�st� ylpeit� is�lt� pojalle siirretty�
sukuosaamista. Mutta yksi ala loistaa poissaolollaan. Yksik��n ydinalan
ammattilainen ei kehu firmaansa julkisesti netiss�, lehdiss�, ei edes asiaa
kyselev�lle lapselleen. Jos katsomme ketk� julkisuudessa ydinlobbailevat,
niin yht��n alan ammattilaista ei taatusti n�y lehtiotsikoissa, netiss�
saati mualla. Vain rahalla ostettavia politikkoja ja vastaavia, jotka eiv�t
erota uraania hiilimustasta taatusti.

Rupesin todella ihmettelem��n miksi. Ja ennenkaikkea KETK� ovat maassamme
nyky��n ydinalan ammattilaisia? Heit� on maassamme tietysti tuhansittain,
mutta keit�? Heille on yhteinen piirre se, ettei n�ill� ole esim.
perustuslakiemme mukaista lakko-oikeutta, kell��n! Toinen keskeinen piirre
on niinik�� lainvastaiset ylipitk�t jopa 12h ty�vuorot ja loputtomat
ylity�jaksot vailla omaa p��t�nt�oikeutta. Kolmas ominaisuus on tekem�ns�
ty�n arkaluontoisuus, mik� tarkoittaa orjallista vaitiololupauspakotetta
uhkailu-ukaaseineen ydinjohdolta. Esim. OL-1,OL-2 ja OL-3 ty�mailla ei
KET��N saa menn� vapaasti jututtamaan tekemisist��n ja m��r�ys on ehdoton,
vaikka maamme pit�isi olla demokratia. Mik� kertoo my�s alan valonarkuudesta
ja h�m�ryydest� enemm�n kuin paljon.

Niinik�� ydinty�l�isten palkkataso on enmemm�n kuin romahtanut loistonsa
p�ivist�. Jos lasketaan Suomen ydinty�l�isten ansiotasot saadaan tyyty� jopa
7 euron tuntipalkkoihin! Reippaasti alle jopa siivoojaminimist� puhutaan
ydinalan ammattilaisistamme keskim��rin kautta maamme! Kun viel� 70-luvulla
ydinosaaja oli huippupalkkalainen ja arvostettu, on h�n t�n��n l�hinn�
kansan hyljeksim� reppupuolalainen, liettualaisorja, turkkilainen, yms.
joita katsotaan pitkin nen�nvartta, jopa kaupan kassalla, koska heit�
arvotetaan toki my�s olemattoman orjapalkkaostovopimansa mukaan
olemattomuuksiin. Ja tieto siit�, ett� suurin osa ei maksa edes veroja,
saati sotuja ja vastaavia alentaa tasoa mutasarjaan kansan silmin.

Vaarallisesta ty�st� johtuvat moninkymmenkertaiset sairastumisriskit
ty�tapaturmista, kielitaidottomuutensa takia tulee valtavasti
onnettomuuslis�riskej�, samoin kouluttautumattomuuksistaan, s�teilyst� ja
vastaavista lis�riskeist� kiistatta puhutaan ydinty�l�isiss�. Hyv�ll� ei
n�ihin pitk�lti "slummiparakeissaan "huuhaleviin" ydinorjin suhtauduta en��
edes harmistuneitten kauppiaitten piiriss�. S�teilyvaaransa takia heill� on
normaality�l�isi� ankarammat
l��k�rintarkastusvaateet jne. Ydinty�l�iselle on kauhistus , jos lapsensa
tulisivat samaan ty�h�n jatkajiksi.Voi vaan h�mm�stell� kuinka nopeasti
ydinalan mega-arvostus on romahtanut nykyiseen mit��nsanomattomuuteensa.

heijastellen sit&#65533; pettymyst&#65533; mit&#65533; ydinvoiman loisteliaitten lupausten romahdettua tshernobyliin on tuottanut. Voi vaan arvailla, ett&#65533; kuinkan n&#65533;in totaalisen pettymyksen ala saa en&#65533;&#65533; jatkossa KET&#65533;&#65533;N kiinostumaan sen yll&#65533;pidosta?

I don't know about warping the pattern so much as making it possibly
hard to tune. You can expect some pretty serious coupling to all
that metal. So expect to have to prune it to a good match, and
maybe vary the exact tie off points of the dipole to move it a few
feet. Sometimes just a few feet can mean quite a bit of difference
in tuning.
As far as NVIS use, I wouldn't worry about the pattern too much.
It may skew it a bit, but I doubt it would really be much of a
problem.

Xray-

Why not use the top of the mast as part of the antenna?

You could either measure 3/4 wavelengths down from the top and bolt-on
the 1/4 wave stub, or measure 1/4 wave down and bolt-on a 3/4 wave main
element!

You could run the coax inside the bolt-on element, and out through a
hole at the matching point.

Thanks, your information is pretty much what I expected. The antenna
will be off the long side of the trailer and I didn't know if the NVIS
pattern would favor one direction or the other. I need a west favoring
direction.

I disagree. Antenna operation (or "theory") is dictated by science. How the mentioned factors affect antenna performance can all be calculated from well established, known scientific principles -- no "art" is required.

However, there are some ways where art does get into the picture. Practical antenna design usually requires tradeoffs, and there isn't necessarily one optimum solution. Weighing the tradeoffs, often including cost and time, requires knowledge and skill, and is a creative process that could properly be described as art -- although the more science you know, the bigger the bag of tricks you'll have for your "art" project. And there are often factors which, although completely deterministic in principle, aren't well enough known or are too complex to practically include in calculations. There, the skill or "art" comes in having a sufficient knowledge of the likely effects of those factors to choose or adjust the design accordingly.

What a lot of people call the "art" of antenna design is just a substitute for understanding. If you don't understand the underlying science or how to apply it, the only tool you have is Kentucky windage and guesswork, often called "art" as opposed to real understanding. While people can very often arrive at a usable solution by using nearly all "art" and little "science", they have more and better solutions to choose from as they replace some of that "art" with "science".

That's interesting. My experience is related to yours, although what I did was bring the mast close to the entire long part of the "J" and found I had to get within an inch before I saw any measurable effects, rcv or xmit. I did it with a 2m copper J.

In your situation, possibly the quarter-wave section is a tank circuit and would need proximity of a mast section of size close to its resonant freq to be detuned by it. I don't know ... just musing. Others will mug me for getting it wrong and that's OK.

More musing: Does the entire "J" have to be upright? Can't I put an elbow where the quarter-wave and half-wave sections meet, so the radiating element is vertical, but the quarter-wave section is horizontal? (In the case of a tower side-mount, this would position the radiating section a nice distance from the tower. Inverted OK.)

Yup. Also applies to rigid coax used for 400 MHz Naval radars.

Sal, I think that the position of the J affects its polarization. Around
1995, I did some informal experiments with an MFJ 300 ohm twinlead J-Pole
and 2m SSB. I used a Yaesu FT-290RII with 2 watts output.

At 2m, polarization is important and I found that by laying the J-Pole
horizontaly, I was able to extend the range of my signals, even if
I layed the antenna on a wood picnic table.

I did not experiment with the antenna in a mixed orientation as you describe
above.

Another posibility is to place a 300 ohm J-Pole antenna inside a rigid
PVC pipe. If the pipe is long enough, the base can be clamped without
affecting the antenna. This does move the feed line from being extended
horizontaly at the feed point to being extended verticaly downward, but
this did not seem to effect the antenna, and the MFJ unit I have is
designed that way.

The 450 ohm ladder line units I have made are built with a horizontal
feed, but that's more lazyness than anything else.

73,

Geoff.

>where the quarter-wave and half-wave sections meet, so the radiating element
>is vertical, but the quarter-wave section is horizontal?

No, it doesn't, and yes, you can.

The quarter-wave matching section may radiate somewhat (it's not a perfectly-balanced transmission line) but the effect should be minimal.

You'll still want to mount the antenna so that the quarter-wave section remains some distance from the mast.

You can extend this approach a bit further, and make a fully- balanced version of a bent J-pole - a.k.a. a "double zepp". This would be two half-wave radiating sections, fed through a quarter-wave matching section.

The coax is connected along the matching section, using a 4:1 coaxial balun.

A further variant of this is an "extended double Zepp" (or "double extended Zepp"), which is two 5/8-wave radiators with a somewhat shorter matching section.

For both the standard and extended double Zepp antennas, the use of a balanced feed allows the "inner" end of the matching section to be grounded to the mast - it can even be part of a metal mast, or can have extensions addd to allow it to be clamped to the mast.

See http://www.tcarc.ca/public/2mdez.php for complete plans for the extended double Zepp. The simple "double Zepp" can be made in a similar fashion, with shorter radiators and a longer matching section.

I built a 440 version of the EDZ for use as a linking-radio antenna for a local repeater system. It works nicely. One thing I'd do a bit differently - I'd actually do the matching (selection of feedline attachment point and shorting bar) after mounting it on the tower, rather than in free space - the tower mast does have enough of an effect on the impedance to change the SWR a bit.

Thanks for the info... I'm should have added that the one I was working with was contained in RF transparent plastic tube. So that's how I can mount the whole thing right next to the mast. Maybe if you were using a traditional copper model, it might be different. But with the one I have, there was no difference with the mast next to the stub section. Though I have noticed similar commercial models do seem to leave an air gap between the mount area and the element.

Hello, Roy and all. While I aggree with the above I think one has to keep in mind that 50 years ago there weren't software MoM (e.g. NEC) and FDTD tools around to implement calculations that don't lend themselves to pencil-and-paper calculation. As a result back then there was considerable "art" (I would call it engineering) involved in antenna design. Hams, too, were coming up with many practical designs back then as well as now. Practical experience was important then and still is.

I think you've just summed up what engineering is all about. Mathematics is an exact science; engineering is not.

That's the difference between hobbyist tinkering and engineering. It's what allowed the Wright Brothers to be successful when others (who may have been close to success) failed. The Wrights took the time to understand the science/physics, performed pertinent experiments and meticulously collected and analyzed data. These endeavors set them apart from their comtemporaries in pursuit of powered, heavier-than-air flight.

The Wrights were much more than bicycle mechanics; in their "off" time they were (aeronautical) engineers. Sincerely,

John Wood (Code 5550) e-mail: wood@itd.nrl.navy.mil

As I understand it, science is trying ideas out to see what happens in
the real world. That would involve "experience" to a certain degree, as
an "educated guess" is involved in the design of the experiment.

Your points are well taken here.

However, I do believe there is a lot of "art" involved. We don't even know what our signals are really composed of. We don't even really know how propagation and movement of our signals takes place though the medium which transports them; And, indeed, we don't even know the medium through which they travel ... if not for brilliant and "artful" men, this never would have occurred.

If this all does not make men stand in awe and wonder of these artistic accomplishment and beauty of engineering achievements, I just don't know what would!

Our imaginations have allowed us to reach out and use powers far beyond the horizons of our vision. Sometime in the future, we will even refine all of this ... as our vision(s) become clearer.

Warm regards,
JS

essentially, that stub is a openwire balanced transmission line, so all the usual rules about spacing of openwire line from things that will perturb the field apply. As Cecil says.. a few spacings away..

Point well taken ... Einstein seemed to have a real "art" of predicting which areas would bear fruit, and a path to follow to deduce their inner workings.

4423. Displacement current

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-18 23:02:43 UTC
From: Art Unwin <ArthurUnwin@gmail.com>
Message-ID: <dcdab5f2-8601-421a-9303-f9bb3994bc51@d10g2000pra.googlegroups.com>
Source record: 20147

As a mechanical engineer I am not particularly qualified with respect
to the following so I am hoping others will discuss it so it becomes
clearer to me.
Reviewing the time of Maxwell it seems his real niche was as a
mathematician
and not necessarilly on par with Faraday, Gauss, Newton and others
that supplied the various observations and formulas with which Maxwell
worked with. From my standpoint he apparently did not give due
preference to the idea of equilibriums as did ALL of his formula
suppliers and considering his object it was not that big a deal. I
then read that the formulas that were condensed in numbers did not
exactly jive! So Maxwell, the mathematician, invented displacement
current which apparently has nothing to do with radiation according to
what I read. Apparently this same current does not create a magnetic
field as the main current does e.t.c. but in mathematical terms it
gave a conclusion to what he wanted to do. From my point of view I
find it odd that a current could flow of a time varient nature does
not include a magnetic field UNLESS the current flowed in the center
of the conductor. I am not saying that displacement current travels in
the center but I do ask those educated in this field if displacement
current has been obseved, measured and is present BEYOND DOUBT? Also
as the generation of radiation is not precisely known at this time,
how could it be said it does not contribute to radiation? Starting
from that presented to Maxwell initially, exactly how did the concept
of a time varying current traveling along a radiators surface yet
without producing a magnetic field pass muster of those who study
such?
Best regards
Art

find some of that oil they soak telephone poles in then coat it
w/sealer

ultimately wood prob wont last as long as some good plastic and
i guess would be heaver stressing the wires more

it will prob still hold more water than a smooth plastic dunno

and prob not have as good insulative prop's but might be moot

I've been able to associate _hash_ , not *static* , to DOT-type roadside
traffic informational signs -- usually the solar-assisted, battery
operated style. My guess is they use some high-KHz power conversion
and/or some not-so-well shielded electronics to operate the sign. The
effect, though, is seen over a quarter mile, or less, section of the road.

What I have found is that the antennas I design tend to mirror the software. The times they have not, I can usually look around and find the thing that causes it, maybe the height I ended up at wasn't the one used for the design, maybe a metal structure, ground characteristics were not the same. etc.

I think we attribute to "art" that which we do not know at the time. As we know more, it all turns into science.

To the group

That's the modern version I was alluding to and not the original
phrase. The part that Maxwell added is not now acceptable and has been
removed. After all, no current or magnetic field that could be
attribitable to Maxwells belated addition to a prior masters findings
was just a whim to satisfy his mathematics and his paper on Forces.The
field or the current has not been ratified
Wilkpedia makes that quite clear if you read the whole article. This
does not render Maxwell's laws as incorrect it just means that like
the weak force he cannot explain the portion which he name
Displacement current even tho he applied mathematical data. All
because he overlooked the term requilibrium and thus assumed that
displacement meant what he termed in his white paper on forces. It was
this reference that shows he overlooked the need for a full wave
antenna and thus the suggestion that force or current deflected off
the end of the radiator back on the path from whence it came., I
suppose that I can now conclude that the book Reflections
based on a hypotheses that was completely incorrect the rest of the
material can be considered suspect. There is no reflection from the
top of a fractional wavelength anttena just a perbatation called
cavitation as with all current flow which is sharply diverted from iys
initial direction.

From the same authority (sic) of wikipedia:
"Ampï¿½re's law with Maxwell's correction states that magnetic
fields can be generated in two ways: By electrical current (this
was the original "Ampï¿½re's law") and by changing electric fields
(this was Maxwell's correction, also called the displacement
current term)."

4435. Log-Periodic Antenna Design

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-19 22:45:19 UTC
From: Rich Grise <rich@example.net>
Message-ID: <pan.2008.11.19.22.45.03.655469@example.net>
Source record: 20159
Cross-posted to: rec.radio.amateur.antenna,sci.electronics.design

My current UHF antenna is a 14" Radio Shack clip lead clipped from the
center of my coax to the venetian blind. I have to hand-adjust it
for the channel, weather conditions, phase of the moon, etc. I can
do this because I can _see_ an indication of signal strength.

Well, with this new Fascist "No More Free TV" crap, I'm gonna need
a real UHF antenna. My budget is exceedingly limited, but I have
a supply of materials (GTAW filler rod, with some coppery-colored
coating, so it solders like a dream, and is as stiff as piano wire)
to build an antenna with.

But I've been searching the web for some weeks now, and I can't
seem to find any kind of formula, except there was this program
I downloaded - LPDA.EXE, which runs on DOS. Unfortunately, it's
in Russian or Polish or Uzbekistani - one of those East Yurp
languages. Here's a screen snap:
http://mysite.verizon.net/richgrise/images/LP-Prog-Output.gif

Which I went through pretty much by-guess-and-by-gosh - can
anybody read that stuff?

There are a lot of factors I don't know about, like "Tau", and
all of the specific designs on the web are flat - something is
telling me I want one of those pyramid-shaped ones, but I really
don't know the difference (between that and flat) - it's probably
something to do with bandwidth or F/B ratio or whatever.

My local library has no ARRL Antenna Book (!), and did I mention
I have a seriously limited budget?

So, how do I pursue this? It'd be nice to have a program that will
calculate the whole thing for me, but am I dreaming? If I want to
send myself to Log-Periodic School, where should I start?

Or, does anyone have a UHF-TV log-periodic design that they'd share? :-)

Thanks,
Rich

>he overlooked the term requilibrium

From Maxwell himself (with correct spelling):

"About the beginning of this century, the properties of bodies
were investigated by several distinguished French mathematicians
on the hypothesis that they are systems of molecules in
equilibrium. The somewhat unsatisfactory nature of the results of
these investigations produced, especially in this country, a
reaction in favour of the opposite method of treating bodies as if
they were, so far at least as our experiments are concerned, truly
continuous. This method, in the hands of Green, Stokes, and
others, has led to results, the value of which does not at all
depend on what theory we adopt as to the ultimate constitution of
bodies."

It would appear that equilibrium (by any variant of spelling) is:
1. French;
2. unsatisfactory;
3. a poorer relation to continuous (i.e. employing time which
equilibrium does not).

Most of the wideband TV antennas I've seen, seem to be log-periodic in
the VHF range, but to use a reflector and a bunch of auxiliary
elements (which don't appear to stick to the L-P taper schedule) for
the UHF.

You might want to consider a different approach - have you seen this
one?

Try this - go to your local hardware or whatever store that sells a
suitable log-periodic antenna with camera and tape measure in hand.
Record it all and then go home and duplicate. Or easier still, buy it,
take home, duplicate, then return for a refund.

Dave.

It's not log periodic but it looks cheap to toss together and they claim
great performance: http://www.digitalhome.ca/ota/superantenna/index.htm

You don't really need a new antenna. If your current antenna is working such that you get a good picture then it should work as a digital tv antenna.

Interlibrary loan is your answer. Your library may not have it, but
someone else's does.

Upisi najnizju radnu frekvenciju : enter lowest frequency
Upisi najvisju radnu frekvenciju : enter highest frequency

Duzina antene: length of antena
Broj elemenata: number of elements

Pritisni taster za proracun antene: press a key to calculate antenna

Duzina 1. elem. length of first element

Pritisni taster za nastavak Press any key to continue

Duzina zavrsnog kratkospojenog odsecka: length of final shorted section
Upisi precnik dipola: enter diameter of the dipole

Upisi ulaznu otpornost (ohm): Entry resistance (weird in original)

Impedanca napojnog voda: feeder impedance (not sure what this is)

Upisi precnik napojnih provodnika: diameter of feeding leeds (my guess these are two bars that hold elements)

razmak izmedju napojnih provodnika: distance between feeder leeds (and distance between two bard holding elements)

You owe me a beer. BTW, its Croatian or Serbian. I kind of understand some 90%.

M

This won't do at all! Two of my favorite stations are ch. 56 & ch. 58.
=:-O

I've got 2-13 covered by my external VHF folded dipole. (It's an RV).

Are the channel frequencies going to be all changed around? I suppose I should email those two stations. I don't know much about DTV, other than I have to buy a damn box and I need a "better" antenna.

Thanks,
Rich

I've heard that there's no "signal strength" meter or anything - it's
either there, or not. With my analog, I can zero in on the proper tuning
(I just futz around with the clip lead until it's "good enough") so
I need something I don't have to screw around with.

Thanks,
Rich

You probably don't need a program, just a decent text book that covers the
topic adequately, which, undoubtedly is what the program writers worked

from, and they might not have got it right! 'Antennas' by John Kraus contains enough detail to make a start and it's probably more general than someone's program which might involve specific choices of some parameter values. So my recommendation would be to find a technical library that offers access to non-members and send yourself to Log-Periodic School as you put it. The IET library in London does this, for free. Do you have an equivalent institution (e.g. IEEE), or a local university that covers electronic engineering? You might be surprised how much access you can gain to libraries to which you have contributed through taxes, or which need to maintain an 'altruistic' public appearance.

The pyramidal form has greater aperture in the vertical plane for all but the highest frequencies. It behaves like a vertically-stacked pair of Log-Periodic Dipole Arrays and achieves a bit more gain. Its pattern in the vertical plane is consistently sharper over a range of frequencies because of the vertical taper, but it is a bit more difficult to design. Not all 'wideband' UHF antennas are based on the LPDA - some are Yagi-Uda arrays designed using NEC and its derivatives, achieving a useful compromise between bandwidth, gain, and pattern shapes. But if you want to include channels below 21 as well as the UHF band, with consistent directivity, then LPDA is probably the only way to go.

Chris

Not after The Big Day. Their frequencies will be changing. Channels
which are broadcasting NTSC in channels 52 and above will be moving
down to a lower frequency.

>I've got 2-13 covered by my external VHF folded dipole. (It's an RV).

A lot of them will be.

Take a look at:

http://hraunfoss.fcc.gov/edocs_public/attachmatch/FCC-06-150A1.pdf

I don't think it's the latest set of assignments but it's pretty well
up to date.

Most digital STB's have a "signal strength" indicator on screen for
each channel.

>it's either there, or not.

That's true of the displayed picture, but not the signal.
Poor (or even too much) signal strength can lead to "drop outs" or
"freezing" of the video image.

Dave.

Yes.
Channels will vary depending upon your country and location. You
should have some sort of official digital TV website for your country
that lists and explains all this stuff.
Australia for instance is:
http://www.dba.org.au/
(server down?)

Dave.

I agree. How much can a coat hanger cost?
If you are really rubbing pennies together, I would ditch the log-periodic approach and go with something simpler, like a monopole or folded unipole antenna. (All you need is wire.)

I just want to mention (again) here that: Hopefully, we'll be able to knock out Ch-5 and Ch-6 from this antenna scenario very soon (and move them to the FM Band, as the FCC is presently considering. I'm a huge proponent of this possibility!

I will try to find the Comments link at the FCC web site so those of you who agree can chime in....

This idea has been floated before, of course. This time it seems to have "legs".
I don't know how much you can read into it, but... the FCC has yet to explain how Non-Commercial Educational (NCE) vertical only stations can obtain authorization for horiz/vertical operation once this DTV transition occurs - which is now less than 90 days away.

There are many pending Construction Permits (CP's) and NCE facilities that proposed Vertical-Only operation in order to protect local ANALOG TV-6 stations. These new NCE facilities will undoubtedly delay construction until a decision is made how to obtain dual polarization licensing. (Due to increased transmitter power requirements and/or RF Safety exposure issues, tower height requirements, etc..)

To date, the FCC has yet to adopt ANY relaxed TV-6 digital protection criteria for NCE FM stations. Instead, these stations must use the old Analog standard - which is MUCH stricter than is necessary to fully protect a Digital TV operation!

And of course, there are only (8) full service TV's on digital channel 6. (Which is a really, really good reason to move TV-6, and possibly TV-5 to the FM band!! -- What a huge waste of spectrum!!) Yes, there are some low-power DTV 6's out there (translators, boosters, LPTV's). Not very many, and all of which are in locations where other spectrum is, or will be, avaialble after the DTV transition...

Anyway, any NCE or CP not near a digital-6 would obviously qualify for dual-polarization. It remains to be seen what the FCC will do about this. Hopefully, they will grow a brain and shift this "un-used" spectrum to alleviate the very crowded FM band.

I don't know if I should hold my breath or not.?

Obviously, you will win this one, long past the time we weed out the idiots ...

When the magnetic field, induced in the skin of the conductor, carrying the rf field is seen by the inner most material is seen, it will induce an electric current into the inner most material ... however true this is, is should be considered "insignificant" to the actual signal which is finally radiated ... there IS LOSS, yanno'! I would venture, it ends up "mostly" heat!

I consider this a poor suggestion for a number of reasons...

Several methods of wood treatment have been used over the years. The three main methods used to be pressure treatment with creosote, pentachlorophenol, or inorganic arsenic salts. These were generally replaced by chromated copper arsenate. Other treatments involved copper napthenate, zinc napthenate, and tributyl tin oxide. All of these methods provide fungus protection and some limited moisture protection.

Creosote, as used for treating wood, is generally coal tar creosote. This material is distilled from coke oven tar and it contains polycyclic aromatic hydrocarbons, phenols, and cresols, all of which are quite toxic and most are either proven or suspected carcinogens.

Pentachlorophenol is registered by the Environmental Protection Agency as an insecticide (termicide), fungicide, herbicides, molluscide, algaecide, disinfectant, and as an ingredient in antifouling paint. Stated simply. it is toxic to just about all life.

Chromated copper arsenate, at one time, was the most widely used wood treatment. Hexavalent chromium and arsenic in any form are both extremely toxic, so newer treatments were developed including ammoniacal copper quaternary. The EPA lists this as a general use pesticide and it is far less toxic than chromated copper arsenate. Other newer wood treatments used today are based on borax and other borate salts. These too are less toxic than the older copper salts.

The oil treatment that "ml" refers to is most likely creosote. However creosote or any other of the treatments described above will not make the wood a good electrical insulator for use as spacers in open wire transmission line. Raw wood or wood treated with any of the metal salts shows a high dielectric loss. Even pentachlorophenol is not very suitable as its dielectric constant is around 8 to 10. But then the wood itself usually has a radio frequency dielectric constant around 10 or more too, even if completely dried. Increases are seen at frequencies below the MHz region, and with increasing moisture. The loss tangent of wood also increases rapidly with moisture content.

The reason that old timers boiled their wood dowels in paraffin wax was twofold. The first was to completely dry the wood, and the second was to provide moisture protection. The preservation of the wood against fungus or termites was generally inconsequential for use as spacers in transmission lines.

Polyvinyl chloride and chlorinated polyvinyl chloride plastics are moderately lossy at radio frequencies but are far better than wood in this respect, and I have seen them used with homebrew transmission lines. However, from the standpoint of RF losses and ultraviolet radiation damage, acrylic plastics are my choice as true ladder line insulators.

One suggestion I have is to look at cheap plastic coathangers. These are about 1/4 inch in diameter and are not vinyl coated wire hangers. Several insulators can be cut from a single coathanger. Since you can often buy these hangers for around $1.00 for ten, a few dollars could provide a good number of insulators. If you don't like the color, spray paint them with Krylon or another acrylic paint. White will provide the best ultraviolet resistance. I would limit my wire size to 16 Gauge or smaller as this plastic is quite brittle.

Try a bowtie (like the one that came with sets) 5 inches in front of a piece
of hardware cloth. Most of the boxes (which are almost free after the FCC
rebate) have a signal strength bar (although with a 3-5 sec. delay)

Years ago they used to make one as a magazine rack that you could pick up
and move around.

It's not a troll. I bought a fair good UHF-VHF antenna,
assembled it and sat it on a saw horse in the driveway
for test, and it tested perfect for 3 channels + ch.34 .
So I set her up using a roof mount and LOST ch.34,
and no amount of rotating got it back.
(I was a pro antenna/tower installer as a kid).

Next I'm going to tape wire on 1/8" panelling and do
experiments ... ugh, I hate trial and error.
Ken

Certainly the copper loss is insignificant in the center but the
radiation resistance is only present for half the time (1/2 WL) !
Thus the input energy is half that placed on a full WL as well as the
radiated energy (I think that is correct) So I suppose you could also
say that the radiation pulse is half the length in time of that from a
full wave antenna.Since the radiation pulse gap is small compared to
what your ear can sample I suppose the same intelligence would get
thru since the sample size is always much larger than what the ear can
interprete. Ofcourse there is the TOA to be considered in any
comparison.This looks all mixed up but I will post it anyway so that
posters will understand what real jabber jabber looks like. If you
look at it from a tank circuit point of view then it really gets
complicated especially this late in the evening

Oh, I see something here ...

I will give this a bit of thought ... damn puzzling. But, not saying
you have something, yet ...

By the way, "what the ear can hear", I "translate" into
milliseconds/nonoseconds/trillo-seconds (or, something only the mind
"can hear") ... but then, you already knew that <sly-smile>

And, still thinking, but then, there is something wrong in your
supposition ... I will find it ...

OK brother, you may not be what I accuse you of ...

But darn, the antenna you bought was designed with certain parameters in mind ... I would seriously doubt you are going to vastly increase performance with the route(s) you have described here ...

Sorry if I made a joke. But, my advise to you would be, if you saved your receipt, take it back! DON'T HACK THE ANTENNA!

Chat with buddies or someone who has had better experience(s) (or, varied experiences) with a better antenna, one which would serve you better.

Without expensive instrumentation and experience of years of experimenting, it is hard to accomplish what I perceive your goals to be ...

I would never say anything is impossible, just what I feel is the best advise I can provide you with in hoping for your best success.

Wish you the best,
JS

Wow, that brings back memories. That is a receiver which came into
being right around when I did (1950's).

The tubes in it alone worth something (can be hard to get replacements
these days, just price them!)

I sat before one of those for untold hours in my younger days ... shame
SW is so empty these days ... :-(It was an EXCELLENT RECEIVER ...

Hi Rich,

Someone else has already provided the translation, so that will take
care of some of the wholes in data entry and reading.

>There are a lot of factors I don't know about, like "Tau", and
>all of the specific designs on the web are flat - something is
>telling me I want one of those pyramid-shaped ones, but I really
>don't know the difference (between that and flat) - it's probably
>something to do with bandwidth or F/B ratio or whatever.

Tau is related to the shape of what you call the pyramid, or more
actually to the angle of the taper. This defines the smoothness of
matching across the span of frequencies you entered into the program.
As you can see, it also relates to the available gain. Another
correlative is it also relates to its length. All of these things are
trade-offs that lend to the rule of choosing what you want most and
giving up on the rest.

I note elsewhere that you wanted something about 1 foot long. There
is a Tau that will give you this boom length, and you got it on the
first guess.

>So, how do I pursue this? It'd be nice to have a program that will
>calculate the whole thing for me, but am I dreaming? If I want to
>send myself to Log-Periodic School, where should I start?

You should start building what your screen shot gave you IF that is
the span of frequency you need (already questioned by other
correspondents).

Why don't you sell your house and move to a place next to the TV
transmitter station. You will only need a piece of wire then.
Or the bare finger.

Must be wet, of course.

Here in the Tyler, TX area, the TV stations are continuing
their analog broadcasts on their previous channels. Their
digital signals are on different channels. When the switch-
over comes, they plan to switch their digital channels over
to their previous analog channels.

Some of the converter boxes have a signal strength
indication. My "Insignia" box does. It allowed me
to find a sweet spot for channel 10 DTV reception
using RS rabbit ears.

I did the same thing and I was surprised how many digital chanels I got.
I was at a dollar store and saw the RCA UHF/VHF loop/ears for $5 and
that gave me considerable better reception.

A very common modification, especially by the Navy, was to add a jack there to monitor the diode load voltage, this makes their regular maintenance much much easier. NAVSHIPS-0967-063-2140 documents this.

Isn't there a Diode Load terminal on the back already?

BTW: That paint job looks awful. Too shiny. I had 2 of those beasts
and liked a slightly worn look a lot better.

They aren't that difficult to tweak to superior performance. I
wouldn't spend more than $500 for one with a good RF deck.

The NAVSHIPS document states that a Dymo label should be affixed by the
jack.

Related to your other comment, I think that the one on the E-place has
been repainted.

My yellow striper came with the decades-old Dymo stickers still
attached. I swear the glues in modern Dymo labels aren't as good.

Tim.

Art wrote:
"I am not saying that displacement current travels in the center but I ask those educated in this field if displacement current has been observed, measured and is present Beyond Doubt?"

Yes.

Displacement current is proportional to the rate of change of the electric field. It moves at right angles to the direction of propagstion.

Like charges repel without electrical conduction so a capacitor passes ac while blocking dc.

A standing wave antenna stores energy in the magnetic field near its center during one half of the cycle and in the electric fields near its ends during the other half cycle.

Dielectric displacement is the electrical strain which occurs in a dielectric medium when an electric field is applied. It is analogous to the magnetic flux density and is expressed in charge per unit area or coulombs per aquare meter.

J.C. Maxwell speculated displacement current produces magnetic lines of force same as conduction current does, therefore an alternating magnetic field would produce an alternating electric field and so on ad infinitum. This was the key to electromagnetic radiation. Hertz later proved Maxwell correct in the laboratory.

Best regards, Richard Harrison, KB5WZI

Actually, I had to construct my own with a broadband MMIC device, to get decent functionality ... however, my mother has an el-cheapo unit she purchased from some yard sale, it/they work surprisingly well!

Location, reflections, etc. can vary ones experience greatly--but hey, they usually beat a wire coat hanger! :-)

I have used the procedure in the following paper:
http://www.urel.feec.vutbr.cz/ra2008/archive/ra2004/abstracts/116.pdf

I slightly modified the design (e.g. I used several different diameters for the elements), but basically I used the same formulae. I did not use their formula for deciding the right spacing between the support tubes to get the right characteristic impedance, because I suspect that maybe it is only valid over a limited range of spacing. Instead, I measured the characteristic impedance of just the tubes with no elements attached on a VNA that could plot impedance vs distance in a sort of TDR mode, and I adjusted the spacing until it was right. I epoxied some very small (roughly 1mm cube) spacers between the support tubes to keep the distance right, once it was adjusted properly. It is important that the space between the support tubes is mostly filled with air, not epoxy or any other dielectric, because the wave needs to propagate at the right speed between the tubes so that the elements are fed in the right relative phase, and this won't happen if there is something with a higher dielectric constant in there. I used those brass tubes that you can get in hobby shops, but unfortunately brass is fairly resistive and I did not silver plate it. I would have used aluminium if it were easier to solder in a reliable way.

The finished antenna had a good return loss over the desired frequency range (sorry, can't remember the numbers) and it did the job for which it was intended although I don't have a measured gain value etc. because I don't have an antenna range.

I have a spreadsheet for calculating the element lengths (in Openoffice.org format) if you are interested.

Chris

Now why did I expect such an answer from you? The Physics World states
that displacement current does not exist
with respect to radiation and you hang on to outdated books and sneer
at modern day advances
Seems like you will never ever accept change

Plenty of paid magazines -- including QST and QEX -- still have many thousands
of subscribers.

A good magazine presents you with interesting new ideas and insights that many
people may not have the time or desire to ferret out from all the information
available on the Internet, and most magazines subscriptions these days are
quite inexpensive anyway.

Take it from a person that used to have over 10 subscriptions a month for mags, printed magazines are dead. The only ones I receive now are the ones that come with being a member in a national association.

Cookbook, if at all possible. Like, element lengths and spacing,
and the angle between the booms - which brings up a question - what
effect does it have when you take a flat L-P and "open it up", like
to a pyramid shape - I was doing a thought experiment with this and
when it's completely "flattened out", (180 degrees between the booms),
it looks like a <drum roll please> Bow Tie!

Thanks,
Rich

"Best Regardses"? ;-)

Anyway, thanks for this - I'm feeling a lot better about this project now thanks to your help and that guy that translated it for me (forgot the name, but he knows who he is - Thanks Again!);

I might even start cutting wire[1] and soldering this weekend! ;-)

Thanks!
Rich

[1] GTAW (Gas Tungsten Arc Welding) filler rod, with some coppery-colored coating that solders even better than copper, about .030 dia., and as stiff as piano wire.

good post, Barry

The suggestion of plastic coat hangers is interesting. I think I might
try home brewing with some pink ones! 8^)

Apparently I'll only need up to ch. 52; have to look up the carrier freq.
on that.

Ch. 14 = 470-476 MHz
Ch. 83 = 884-890 MHz I think.

Now all I need to do is the algebra. ;-)

52 - 14 = 38
38 * 6 = 228
228 + 470 = 698
698 + 6 = 704

Cheers!
Rich

Your clip lead is too long. Try 1/4 wave.

I got good reception using a 4 1/2 inch length of 24 gauge solid poked
into the F connector for a (line of sight) 45 kW station, 20 miles away.
(Most of the local stations run in the 500-1000 kW range).

FS: A brand new, never used, completely assembled W5GI Multi-band Mystery Antenna. These are great wire antennas(see e-ham product reviews). I just don't have the room to put it up. I paid $100 for it and will sell it for $59 plus shipping. See W5GI's webpage for more info. Thanks, Charlie Hugg, K5MBX

Orfanidis's book on electromagnetic waves and antennas is online, and
covers LPDAs.. Kraus is better, but you'll have to fork out at least
$20+shipping for a used copy. Kraus *is* my recommendation if you have
to have a single antenna book, though.

I think a bow tie's design is actually motivated more by one of the "standard" ultra-wideband antenna designs, that of a pair of opposing cones touching each other at their narrow ends, being translated down into 2D.

QST is not really a magazine, but a membership in the ARRL and the magazine
is 'free'. I don't subscribe to any electronic magazines now, just two
others and I am dropping Comsumer Reports soon.

Not that I agreed with Wayne Green, but I did like the older 73 Magazines.
Also the Ham Radio magazines. QST is too full of contest/DX and other
things for me, but I do see how others would like it.

No, that's "Best Regards's". It's the possessive, not plural, form of "Best Regards". I think the grammar is part of the same dialect as the verb "destinate" (as in "I've just destinated"), but you'd have to ask Richard about that -- he's the one with the English Lit degree.

It may not take too much antenna. I picked up one of the converter boxes
and hooked it to a 432 mhz beam at 70 feet and got 21 stations on the auto
tune. Then to a 9 element M2 2 meter bem and it picked up 29 stations.
This was at the end of about 130 feet of low loss rg-8 size coax and then 25
feet of rg-6.
Several of the stations were the same transmitter,but differant chanels on
the TV.

Standard, indeed; this antenna is known as a biconical. It has excellent wideband response making it ideal for EMC testing. Most good antenna texts such as that by Krauss give a detailed analysis of the biconical antenna. I see no relationship between its design and a fractal design other than both are wide bandwidth antennas.

The bowtie antenna which Rich and others have mentioned is a "flattened" form of the biconical. If the bowtie is bent along its major axis, it makes an excellent wideband driven element for a corner reflector antenna.

Another suggestion: "They" make fiberglass driveway-marker rods which
seem to come in either 4' or 6' lengths. The ones I've used are 3/8" in
diameter and usually are painted International Orange and have a
reflective strip at the top. (Maybe more readily available in hardware
stores for "country folks" who need to come home down a gravel road in
the dark, with 2' of freshly fallen snow...)

I've not used these for feedline spacers, but they seem to be another
choice for that application. I've used them for VHF antenna
construction -- for both fixed and portable antennas.

Thanks for the details, Barry... tell me though, then, is a discone just a biconical with a ground plane used to create the (image of the) missing cone?

Yes. It will have less gain than a biconical and the bandwidth is slightly
more restrictive too. But it is much easier to construct!

Sorry, it doesn't. Among the claims, trolls for investors, and
testimonials, where is the quantitative data showing that a fractal
antenna is in any way better than a bow tie, in what ways, and how much?
In other words, exactly where is the evidence on which you based your
statement?

I fully agree. 73 and ham radio magazines were not put aside in the
first 30 minuits
as they had a lot of interesting articles. Radcom and QST have just
one article for the ham to read
and the rest is just fluff and district officers reports. The articles
by QST seem to come from a
particular type of ham who agree with the small group of overviews
that pre vet the articles.
How long as it been since you have seen an article about radio that
was contrerversal or even challenging the statuc quo?
You will continue to see articles on code keyers, soldering coax
connectors, power supplies e.t.c for the next decade,
they all abhor change
Art

Hi Rich,

Tacking the new-age term of "fractal" to antenna does not
automatically bring:
1. Widebandedness;
2. Gain;
3. Small size.

The link above fairly confirms it in the fog of offering.

I could expand upon this - but the interest of those who become
suddenly engaged with the topic rarely translates into a meaningful
discussion, and never leads to an actual construction.

I've seen several programs that will help you calculate the precise dimensions of a single-turn loop, given the composition of the radiating element, its thickness, and so on. However, none of these programs are written to cover the case of a two or more-turn loop.

Does anyone know of a program that will offer guidance in the construction of a two or more-turn loop?

Thanks,

Steve

The difference is that you did agree with Wayne Green on what to put in
a magazine and he was smart enough to fill 73 with things that everyone
wanted to read.

I enjoyed reading his editorials as they were very entertaining.

I doubt that he intended them as such, but if you read them or not, agreed
with them or not, you still could get a "good read" out of each issue.

Hi Steve,

For transmit, there's nothing to "gain" by it.

Success generally floods the marketplace and few complain about not
finding resources to make a knock-off.

It doesn't.

I have two converter boxes, one Magnavox, one Zenith. I just now tried my local stations with them using a straight 24-inch alligator clip lead as the antenna. Location is a residential garage in the San Diego suburbs. Stucco walls, metal garage door closed, overhead fluorescent lights on. Transmitters in three different locations.

All the UHF locals came in, 10 transmitters with about twenty total programs. The one low-power VHF did not. Looping the clip lead back and clipping the end to the F-connector produced about the same results. (Lost one TJ station.)

When I "upgraded" to a POS 2-bay bowtie in the rafters (about 8 feet up), all eleven locals came in, plus KCBS from LA . On the Zenith box, arguably a better unit, I got two more LA channels, although one of them had some intermittent freezing and tiling.

If even poor antennas work well, why all the whining?

Search for Reg Edwards programs. RJELOOP3 is probably what you want.
I'm assuming here that you're talking about loops that are very small
compared with a wavelength, which may offer advantages as receiving
antennas for low frequencies.

Cheers,
Tom

Looking for outdoor omni "whip" antenna for 2.4 GHz.

Is there any reason to not go for the greatest gain antenna, given that cost
is not too important (within reason)?

There are scads of these on the 'net. I'm looking for someone who has
experience with one or more of them and can make a recommendation for one.

Thanks,

There are 1/2 wave antennas on the market which do a decent job. I have found their biggest problem is the coax the manufacturer ships with them--too low of quality and too short.

Here is an article on one you can homebrew yourself, from ANY USB wifi card:
http://tinyurl.com/6xdfav

-- or --

How about one of these?:

http://tinyurl.com/5ocovb

used with a 25 ft. USB extension cable, I use it when traveling. Plus, you bypass the need for expensive/lossy SHF coax ...

Hi, not actually 2.4 Gig WiFi but cellular wireless modem card. I
bought one of the small verticals with a magnet mount and cabling for
about $15 ppd as I recall. My situation is that my house is built with
concrete/rebar construction, metal 'persiana' windows and screens and
its hard to get a signal out of here even on the various cellular bands.
I think the highest band there is 1.8 GHz.

I didn't go for gain since the path to the site is only about 1.3 miles
away so I opted for the little guy, about 7 inches tall, that just sits
on the roof. On the other hand, a friend in a different location got
himself into all sorts of problems with reflections and multiple tower
sites and is now looking for a directional antenna to minimize the clutter.

Another consideration is the vertical angle between you and the site.
The "high gain" verticals (I've seen ones claiming 14db) have a rather
flattened omni pattern so that if you have to look upwards to your
intended site you might find the gain to be considerably less, if any.

Hello Steve,

You probably did some loop calculations and found that in a transmit case the voltage across the tuning capacitor is very high (and bandwidth is limited). Also for small loops, most input power is lost as heat due to copper resistance.

When you make a two turn loop, the radiation resistance will increase with factor 4. So with half the current through the loop, the radiated power is same (as for a single turn loop). When the 2 turns of the loop are relative close together, the inductance increases with factor 4, hence the reactance.

The current has been halved, but because of the reactance, the voltage across the tuning capacitance will be 2 times the value for the single turn loop with higher probability on corona effects. An advantage can be an almost 4 times smaller tuning capacitor.

One may expect that the loss resistance due to heat of a two-turn inductor will be twice as high (w.r.t. single turn case). This is not true; the loss resistance will be more then twice as high because of proximity effect. The current will not equally distribute along the circumference of the tube/wire. So the efficiency of the loop will be less then twice as high (w.r.t. single turn case).

When the turns are far apart (with respect to wire/tube diameter), inductance will not be 4 times higher and proximity effect will be less. You will get better performance than the single turn loop made of same diameter tube/wire. The result will be the same as when you place the two turns in parallel. Inductance will decrease somewhat (hence lower voltage across capacitor), AC resistance also, hence radiation efficiency).

There is an "however". When you make a single turn loop from flat strip that has the same width as the length of your two-turn loop, you will notice: 1. reduced AC resistance (because of the significantly larger circumference of the flat strip with respect to a thin round tube, 2. inductance will decrease (H field lines have to take a longer path around the wide strip), 3. radiation resistance will not change with respect to a single turn loop from wire/tube.
This results in higher efficiency and increased bandwidth. The overall result will be better then for your two-turn loop. I think that is the reason why most programs are for single turn loops.

So for the transmit case, given fixed diameter of your loop, the larger the copper surface (=length*circumference), the better the efficiency. Best thing to enhance conductor surface is to use very wide flat strip (high wind load), or multiple wires (with some spacing in between) in parallel (limited wind load).

Off course for the receive-only case, a multi turn loop can be helpful as you can use a smaller tuning capacitor.

Best regards,

Wim

Hummm. New call I see...
I liked the old one better, but of course, I'm biased.. :/

Actually, I went back to my original Technician thru Advanced callsign. I'm tired of repeating nm2k fifty different ways from Sunday and then they still can't say it because they learned the alphabet with mn in that order and not nm. On CW they think I'm finished sending with the K at the end of nm2k, then they ask me what kind of callsign is nm2?

Besides, my wife and I had/have consecutive callsigns with N2ECV and N2ECW.

I had nm2k for 23 years. Now it is someone elses turn. <G>

My Webster's unabridged dictionary gives the following
examples of the correct way to pluralize numbers.

"figure 8's", "the 1890's", "the 20's"

73 is a number that stands for "Best Regards"

73's would be "Lots of Best Regards".

Yes, I know there's nothing to gain in terms of performance. However, I have very little space to work with. I have a 1 meter diameter loop installed in my (tiny) attic that works very respectably on 10-30 meters. It won't get me onto 40 meters, though, and getting onto 40 is either going to require a much larger diameter single-turn loop, a two-turn loop, or a much more robust capacitor. Trying out a two-turn loop seems like it would be the easiest and least expensive alternative, and I already have the copper tubing I would need.

Whip antenna? What is this, for a vehicle? For a stationary location it seems like it'd be an extremely bad idea to use an antenna that 'whipped' around.

> Is there any reason to not go for the greatest gain antenna, given that
> cost
> is not too important (within reason)?

Alligator effect. Wide mouth receiving everything. If you don't need to pickup everything then why bother? It just makes it harder for your WiFi router to cut through all the noise of distant stations it doesn't communicate with. Get the right antenna suited for your installation, no more, no less.

Which leads to the constant request, when you ask a question POST WHAT GEAR YOU'RE USING.

In your case it would also help to define what sort of connection you're trying to make. Point to point, metropolitan, etc.

Now that the FCC has given a green light to whitespace device deployments (particularly those that rely solely on spectrum-sensing technology), you may find you need a better antenna than a simple loop, bowtie or coat hanger.

For those of you who are not following the issue, a quote in this week's TV Technology pretty much sums it up:

"MSTV (Maximum Service Television) told the Commission Oct 31 that the least the FCC could do is subject the devices to rigorous testing beforehand and ensure fair and reliable tests to prevent interference to DTV. In a filing, MSTV also attacked the FCC proposal that a device should be able to detect signals as low as -114 dBm, a level MSTV equated with setting a smoke detector to only be able to detect a raging fire."

Whitespace devices will also cause great harm to wireless microphones, particularly older models.

A friend of mine is a dispatcher for police/fire/ambulance/etc., in my area. Her 10 code often requires her to use the "10-73" from this ten code--which is a "smoke report."

So, thanks for clarifying this for me. I simply took the 73's on many of the posts sigs as a sign they were "blowing smoke" (actually, "Lots of smoke!" :-)), and giving me fair warning! <straight-face>

I don't have data. I think the home made TV antenna in the video, is very much like a bow tie,
and could have better bandwidth by making the elements different lengths. The gain factor is going to be narrow band since the feed length is constant. I would have also used 12ga copperweld or solid copper. You can also get closer to fractal by using many more different sized elements.

I believe, he is speaking of rotating the flat surfaces of the
conductor(s) 90 degrees to what a "slinkys'" orientation places them at.

In which case, "mondo-capacitive loading to the 'environment'" is also
introduced ... while minimizing capacitive loading between turns.

Regards,
JS

Personally, I have my own version, it uses a fixed resistor (you will
need to use a fixed ascii font to view it properly):

```
---
|
| <<-- telescoping whip
|
|
|---------------------- <<---
/ |-------------- coax
\ |_______________ <<--
/ <<----- 50 ohm, five-watt or better non-inductive
\ |
/ |
| |
----- ---
--- - <<-- ground
-
```

Much superior design! No moving parts. And, for the low price of
$49.99 USD, I will personally construct one for ya' and even pay the
shipping! LIFETIME GUARANTEE TO BOOT! :-)

If you need a different impedance than 50 ohm, just state so in a note,
along with your check! :-P

Sorry the ascii text does not convey just what a miracle this antenna is!

Regards,
JS

All else being equal, a lossless 'ground plane' type antenna, be it a monopole developed from a dipole or a discone developed from a biconical dipole, over an infinite ground plane should exhibit 3 dB _more_ gain than the symmetrical 'parent' form of antenna. This is because its radiation pattern is limited to half the solid angle of the parent (e.g. only the space above the ground plane). Then for a given number of watts fed into the antenna, the power-flux density must be greater in the region where it can radiate. In practice, the ground plane isn't infinite so there is some 'undercutting' of the vertical radiation pattern, but the gain should still be somewhat greater.

The apex angle of the cone in a discone can be chosen to yield 50 ohms terminal resistance over part of its usable bandwidth, and that angle is different from the apex angle(s) needed in a biconical dipole for the same impedance. The usable bandwidth is always limited by the limited flare-length of the cone(s) and usually also by the accuracy of the apex or apices where termination is made.

Who and where?

Be reasonable. Free space is normally nonconductive. It is a good insulator or dielectric. Light is by all accounts an electrromagnetic radiation. We readily see light from sources throughout space.

Michael Faraday (1791- 1867) wrote:
E = F/Q where E & F are parallel vectors. E = the electric field strength in force per unit charge and F is measured in newtons per coulomb.

Electric charges` force on each other are readily measured. Likewise, magnetic forces` influence on each other and upon electric charges are readily measured.

Radio waves as Terman says:
"---travel with the speed of light and consist of magnetic and electrostatic fields at right angles to each other and to the direction of travel."

Electrostatic does not mean stationary.

There are no conductors in space suited to support an electric current for wave propagation, therefore it is the invisible but readily measurable electric and magnetic fields which invoke action at great distances.

Best regards, Richard Harrison, KB5WZI

No, a 'standing wave' antenna stores energy in a magnetic field that has peak intensity at the positive and negative peaks of current, and energy in an electric field that has peak intensity at the positive and negative peaks of voltage. Energy is stored in both fields throughout each cycle (except at the zero crossings of current and voltage, of course) and for the fields associated with radiation the peaks of current and voltage occur at the same times. For a dipole-type antenna, both fields occupy the region of space surrounding the antenna elements. The magnetic field is strongest near the part of the antenna where the current is greatest, the centre of a dipole (with length up to half a wavelength) as stated above, but the electric field is not necessarily stronger near the ends of a dipole's elements - it is developed between them. The formulae for all the field strengths can be found in reliable text books such as Kraus 'Antennas'.

I concur. I like the Huntgate solution but prefer to use Ethernet for the
run. However, there is a problem with using a high gain omni antenna in an
urban area where there is a lot of channel loading. Your throughput drops
because you are spending a lot of time with collision avoidance. This might
work at night, but not if everyone leaves their wireless up all the time.

WiFi was meant to be short range. When you improve your range, you compound
your interference problem exponentially. If you use a Pringles can you have
a big advantage because it is as if you moved your low gain antenna closer
to the AP but you still have the problem of the connections the AP hears but

you don't hear and can't avoid colliding with. At least you aren't being bombarded with broadcasts.

Simply put, there are limitations to performance when you put yourself in a crowded situation.

Wouldn't that take more room than a slinky per turn?
His attic is very small!.I think he would be much better placing the
turns as close together as possible
to obtain axial directivity. The only mod required to the slinky is to
ensure the number of right hand turn loop
are equal to the number of left hand turned loops. Feed could still
be at the center and depending on the amount
of wire used it would radiate like a dipole or axially. What this does
is cancel the lumped loads created in manufacture which
Wim suggests is a problem ie the two supposedly lumped loads will
cancel
such that you have several wavelengths of wire helix style and no or
repetitive points of none reactive impedances. He could ofcourse
place
the windings in a vertical direction to obtain an omnidirectional
pattern and utilise the available room to a maximum.
A lot depends on what frequencies he wishes to use as to what form the
radiator becomes.
Best regards
Art

And if you aren't a member, you aren't in on the joke?

With all the added capacitance to the elements, I have little doubt that there would be lots of resonance's, and it would be cool to choose the geometry to bring about the proper feed point impedances, but these things can never be gainful with all the losses introduced.

Neat idea for specific applications like little pocket toys, but certainly not the answer to everything.

I wonder how the Limo's will deal with DTV in motion.

> I don't have data. I think the home made TV antenna in the video, is very much like a bow tie,

Comparable to a 4 bay bowtie. Maybe 6db gain. Brazing rod would be a little lighter and wouldn't rust. Would work much with a reflecting plane and above the house clutter.

Twin lead could make a comeback since there won't be such a worry about the low band interference issue. Actually much less loss than coax. I may yet change over to 300 ohm window line on my bigazz deep fringe at 40ft and switch it to the ham shack for 6/2m SSB work and DTV DX. TV DX won't be dead, you will just have to know where to find it

Hi Steve,

As offered by another corespondent here, the work of Reg Edwards
revealed that a multiturn transmit loop, designed for "efficiency's
sake" is never as efficient as a single turn loop. There are, of
course, any number of alternative designs if you don't want
efficiency. Many of those designs are touted here in this group -
usually appended with hitherto unrealized advances the masters were
never aware of. Usually, the longer the thread, the poorer the
design.

You have already recognized the significant variables you would have
to attend to to go lower in frequency - it is not for the faint of
heart and the Q keeps climbing.

I forgot to mention that a similar type radiator is shown in Antenna
Applications
Reference Guide by Johnson and Jasik with slight modification. This
design was succeeded by the helix antenna
to obtain circular polarization which is now universal with respect to

space communications.
The beauty of this design is the multiplicity of resonant points and
the use of different frequencies.
The economy of space is some what altered by the need of multi
wavelength of wire because
of slow wave.but then it enables axial directivity. There are many
hams who are delighted by the slinky performance
and they are still sold in huge numbers to the ham community, so it
must be performing!

Maybe... when it's new, of the right type (e.g. tubular), clean, dry,
and carefully installed.

My understanding is that the performance of 300-ohm twinlead
installations tends to deteriorate significantly after a few years
(sunlight and ozone attacks the twinlead, and dirt and pollution
builds up) and during wet weather.

remember, art believes space is full of magic jumping diamagnetic levitating neutrinos, obviously they carry the charge so there is no need for displacement current, only the weak force.

I agree.

On page 40 of Kraus` 3rd edition of "Antennas" is found:
"For a 1/2-wave dipole antenna, the energy is stored at one instant of time in the electric field, mainly near the ends of the antenna or maximum charge regions, while a 1/2-period later the energy is stored in the magnetic field mainly near the center of the antenna or maximum current region."

My preceding statement was before reading Kraus:
"A standing wave antenna stores energy in the magnetic field near its center during one half of the cycle and in the electric fields near its ends during the other half cycle."

My statement lacks clarity and precision. I am a poor engineer who has never worked as an educator. Chris` point? Close but no cigar? OK, I deserve the critism.

Last time I used twinlead, except for fiddling around, was on the family
TV antenna installation using an Allied Radio Corodized VHF antenna,
with Beldon Super Permaohm 300 ohm shielded twinlead. Good stuff.

I hardly dare to say it but, actually that's incorrect for the radiation field (which is what I wrote about). The radiation resistance of an antenna accounts for its ability to radiate power into the surrounding space and, like all other resistances, the peak of current co-insides with the peak of applied voltage - so one doesn't occur '1/2-period later' at all. What's described in the passage above is the situation in respect of the temporary storage of energy in the 'reactive near fields' corresponding to a reactive component of the terminal impedance, not the radiation resistance. I would expect the latter to be of greater importance to those interested in communication.

I wouldn't disagree with the statement that stored energy is concentrated in the regions near the 'maximum charge regions' but if you plot the equipotent lines around a dipole and equate the amount of energy stored to the electric field strength it illustrates that the spatial distribution of energy in the electric field is similar to that in the magnetic field ... as one might expect.

Art, where did you get the idea a slinky had "axial directivity" at
40M. I hazard a guess that it was from reading about helix antennas.
The axial radiation is only true if the diameter of the helix is
fairly large, on the order of 1/pi wavelength usually.
This would be a huge antenna if designed for the frequency(40M) that
the OP was asking.
I can see how this misunderstanding led you to your shoebox
antenna.design.

Gee I hope you arent spending good money filing for a patent on that
thing. I understand that can cost a couple of thousand these days.
However it would be interesting to see you get it.

Jimmie

Not so. I am willing to believe what modern science say that the
aether is filled with
a circulating magnetic field thru which particles can pass. If that is
what they think that is fine by me.
After all there must be something inside the arbritary border of the
Aether to prevent it collapsing per Newton

That's a good explanation. It might help some people to visualize the process by comparing it to a series RLC circuit, which its feedpoint impedance resembles over a moderate bandwidth. In both an RLC circuit and an antenna, the current and voltage aren't in phase, but they're not exactly in quadrature (90 degrees out of phase) either. This means that during each cycle, some of the energy entering the RLC circuit or antenna is stored and some is consumed. In the RLC circuit, the stored energy is stored in fields in the capacitor and inductor; in the antenna, it's stored in fields near the antenna -- the near field. And the consumed power is dissipated in the resistor in the RLC circuit; in the antenna, it's radiated. The antenna's equivalent to the RLC circuit resistance is, of course, the radiation resistance, which "consumes" -- radiates -- some of the applied energy each cycle.

Faraday should have written that E is in units of newtons per coulomb,
as F would obviously be in newtons.

That`s chris` prerogative. Note the near field is also called the "induction field". One reason, its energy returns to the source each cycle. The far field emergy has escaped or radiated. Its energy appears as a resistive load on the source.

Best regards, Richard Harrison, KB5WZI

Jimmie
The diameter of the helix and the pitch of the helix is only a couple
of terms that Krauss applied to a helix antenna which is not in
equilibrium.
He also assumed too much when he assigned more gain to a helix that
could be attained by a antenna not in equilibrium which I strongly
suspect is the belief he had in the displacement current. Krauss did a
lot of pioneering work but the passage of time have pointed to many
errors.
If a helix winding wire is less than a couple of wavelengths then the
radiation will be at right angle to the axis. If the wire length is
above two WL preferably 7-10 WL the radiation peak will be axial
regardless of the diameter or helix angle as long as the radiator is
in a state of equiulibrium. the law that I continually state from the
extension of the Gaussian law of statics which I derived. Wind two
inductors with a common wire but wound in opposite directions and view

with MFJ 259 or alternatively review ARRL publications where they show a fully wound dipole and then start thinking for yourself instead of jumping to unfounded conclusions. I also read that the reason that the EH antenna and the cross field antenna does not work as expected because they were founded in part on the non existant displacement current b ut I have not followed up on that from first principles so it is just a statement

I had that problem with my last call.. Sorta.. "WD5CJL"
If I just said "L" , often they would think I said "O" for some
reason.
Some do have a problem telling NM apart if the noise is high or
whatever.. I always use the standard "november -mike-five-kilo"
phonetics if they get confused.
I usually avoid the other versions.. IE: numb-minded-five-kinky"
as an example.. :/

Art:

The way I "read" him is, he now has a 1m loop, SINGLE TURN (equiv. to resonating a 8-12+ ft. whip on the hf bands?) able to do 10-30m--with WHATEVER "matchbox" he is choosing to run ... he is contemplating on adding a second 1m turn (to add 40m capabilities, apparently) ... are we on the same page? ... and, loops are NEVER omni-directional! Well, other than one constructed to radiate/receive in the plane of the loop and run in a horizontal plane, would, perhaps, do some type of omni-horizontal-polarization?--and a 1m at 10-30m, it ain't such an animal! (well, maybe-kinda-sorta, but I DON'T KNOW! I would have to get hands-on-experience before trusting a ventured reply ... any books I have ever laid hands on are vague on all this ...)

Personally, the only time I have ever used a loop is for AM broadcast radio and direction finding (fox hunts) in the 10 to 2m bands, and, I did NOT want omni capabilities! ... well, there may have been one or two--but so long ago they escape memory ... I never did "like them."

Or, in other words, I am NOT a "loop guru" ... :-(

Anyway, after all that verbiage, the cut-to-the-chase: "I would think a slinky and what he has are two 'different species'."

You mean, those "antenna/rf-magnetic-fields" are NOT leaving the
radiator at the speed of light, but being "stored in the ether?", to
then collapse and induce an electric field back into the element which
first generated-such? <sly-grin>

Sorry, I know, this will be perceived as "troll-territory." :-(

I stated Slinky only because I thought that was what Wim was proposing
and then went from there
If the poster now has a loop without a capacitor that is resonant on
40M then a second loop wound
in the opposite direction when added to the other loop. If he is
adding a lumped load in the form
of a capaciter then all bets are off as Maxwell doesn't entertain
lumped loads in his equations.

Interesting ...

EVOKE:
arouse: call forth (emotions, feelings, and responses); "arouse pity"; "raise a smile"; "evoke sympathy"
provoke: evoke or provoke to appear or occur; "Her behavior provoked a quarrel between the couple"
educe: deduce (a principle) or construe (a meaning); "We drew out some interesting linguistic data from the native informant"
raise: summon into action or bring into existence, often as if by magic; "raise the specter of unemployment"; "he conjured wild birds in the air"; "call down the spirits from the mountain"
suggest: call to mind; "this remark evoked sadness"
wordnet.princeton.edu/perl/webwn

INVOKE:
raise: summon into action or bring into existence, often as if by magic; "raise the specter of unemployment"; "he conjured wild birds in the air ...
cite as an authority; resort to; "He invoked the law that would save him"; "I appealed to the law of 1900"; "She invoked an ancient law"
appeal: request earnestly (something from somebody); ask for aid or protection; "appeal to somebody for help"; "Invoke God in times of trouble"
wordnet.princeton.edu/perl/webwn

Gee, I am "feeling for you", just can't "reach you", but then, you already knew that ... :-(

> Is that correct?
> Art

Sorry Art, I am not talking about a slinky.

I am just talking about a multi turn (2 turns) loop where overall wire length is < 0.25 lambda so you can assume that current in wire is constant along the length. It must be tuned by external capacitance.

Regarding the strip. When you take a 3.14m long 20cm wide thin copper strip and make a loop of it (1m diameter), it will have a better efficiency then when you take 6.28m copper tubing with Dtube=2cm and make a two-turn loop (Dloop=1m, turns 18 cm apart).

In the strip case, the current has more circumference to flow (40cm) instead of 6.28cm for the copper tubing. AC resistance of copper

tubing will be about 10 times higher. Off course, current in two-turn loop will be half (for same radiated power), but still heat losses will be 10*0.5^2=2.5 times higher (for the two-turn loop).

When both loops have good efficiency (so radiation resistance dominates), the strip loop will have better bandwidth as flux path is longer and therefore results in less inductance.

I hope this clarifies my posting.

Best regards,

Wim

> you haven't presented anything that you derived... state the equation.

Oh come on David I do not work for you, do it for yourself as you have
a superior background than I do.
If you are proficient in mathematics check out the addition of
displacement current of Maxwell and review it as just that.
a current in circular foirm that DOES generate a displacement
magnetic field such that it displaces a charged particle
from the surface of the radiator. This eddy current has the units of
current which somehow would match the
description of the "weak force:". Maybe the other masters needed to
include this same addition If your math is up to it
why not check that out? You stated previously that you wanted to know
where the weak current equation is so, now you can start on a series
of
removal or added equation to all the formulas supplied to Maxwell by
previous masters and determine for yourself,. The correct units are
there
so that all equations jive with each other sfter manipulating the
supplied laws.
Stae equation you ask?> A radiator can be any shape, size or elevation
when providing the maximum radiation as long as it is in equilibrium.
I believe that the helix goes along way in supporting that statement
which comes from changing a static field to a dynamic field and
confirmed by existing antenna programs based ion Maxwell';s work.
Ofcourse you can declare antenna computer programs are in error and
salvage your credability or place such a statement in the practicable
book that you are writing! After all if it is printed in a book it
must be right.......right?

You know, JB? Ever since you have entered here, I found you to be an idiot? I mean, I don't want to be rude, or anything ... now, you have fertile ground to prove me wrong! I will pause for the words of wisdom which change my life ...

But then, what are you? Do you have a book you quote from? Do you have any antennas you are experimenting with? Are they ancient ones, ones we have seen a dozen times before now? Are you one who wishes to "buddy up with one(s)" already quoting one (or more) of the "great minds of yesterday?" Are you here to quote from books for the poor?; i.e., those who can't afford the books so you "throw quotes out, and bits-of-wisdom for ignorant and starving minds?" Are you here to "enlighten my mind?" Are you here to enlighten us all?

What are you about? Whatever it is, please get on with your "big bad self." My patience grows thin and I am beginning to think you have NOTHING to offer other than I have already seen? (and seen, many, many times <yawn>)

But then, a pause, let us be "be-dazzled!" ... your forum awaits you ... I now hang upon your every word! :-) Go forth and cure my ignorance!

Regards,
JS

"In what way is it (an electrostatic field) not (stationary)?"

Terman was refering to an electromagnetic (radio) wave. It is a peculiarity of "old-speak" to call an electric field an electrostatic field.

As Cecil reminds us, radio waves are always in motion. But, their superposition may produce a stationary wave called a standing wave.

The only "evidence" I have is a "testimonial" by the guy who invented it,
on some PBS show. And they claimed that that's how they pack so much
antenna into a box the size of your thumb. ;-)

And, having a passing familiarity with fractals, it just sounds eminently
plausible to me. :-)

Cheers!
Rich

Where I'm sitting here in Whittier, KABC 7 is so strong I can get it without even a cable plugged in!

It's 50, 56, and 58 I worry about; 2-13 and 28 are covered; I'm looking forward to seeing if my new bowtie (from that youtube video, but with ER708-2 x 1/16 filler rod) will pick up PAX on 30. They have some nice oldies sometimes. (I also have some of the ER708-2 in 0.045".)

I'm gonna solder it together and hold it to the board with brass thumb-tacks. ;-)

Just for reference: http://www.youtube.com/watch?v=EWQhlmJTMzw

Cheers!

Since you have included the HAM radio newsgroups as your first choices,
with the Internet Wireless as your last choice,
then - as was mentioned above - what are you trying to accomplish
with this 2.4Ghz outdoor antenna ??

Since you used the term "whip" it tends to imply some physical motion or
vehicle,
vs a "vertical" which implies a stationary location.
And both imply a omni pattern - like a general Access Point -

Maybe I was to quick in replying. Hope I haven't ruined your week end.
My car battery went down so I filled it with distilled water and tried
to charge it
But the meter on the charger is not working/moving so I am not sure if
it is charging,
Strike the two charger together and get a spark but the weather is
below freezing
Don't know what to do now. I am confused Maybe the water is frozen

Yes these cans work well ; the problem is the type and length of coax .
A suitable arangement is a WiFi router near the antenna (if necessary in
a wx proof box) with an ethernet cat5 cable running to the equipment.

Another possibility is a USB WiFi adaptor in the focal point of a
satellite dish with a USB to ethernet converter.

But Cecil has never said you can have current flow without a magnetic
field!
So now one must determine where the reflection occurs and science
puports that it is not at the end of the antenna!
Thus the term "standing wave" must be thougherly defined in line with
the newly disclosed facts so that all jive.
Also, Gauss never assumed the wave description over a particle
description, The answer regarding waves and particles
with respect to radiation has not yet been resolved by the scientific
community because of the Maxwell additive dillema.
And "Old speak" doesn't cut the mustard in present day debate. It is
completely wrong to call a static field an electrical field.
It is either a static or a dynamic field so guessing what Terman
really ment or meant to say just does not have any standing.

Flat conductors aren't as attractive as they look at first glance. The problem is the same proximity effect mentioned earlier in the posting. Current is distributed evenly around a round conductor (assuming the perimeter is a very small fraction of a wavelength), but not along a flat strip. Because of proximity effect, the current is much more concentrated near the edges than at the middle. The result is that the resistance is considerably higher than for a wire with the same surface area. In figuring an "equivalent diameter" of a thin flat strip in order to get the same L and C properties, the rule is that a strip is equivalent to a wire whose diameter is half the strip width. This means that a strip of width w or total "circumference" 2 * w is equivalent to a wire with a circumference of pi * w / 2 ~ 1.6 w, in so far as L and C go. Since the same phenomenon affects the inductance and resistance, this would also be a good working rule for estimating the relative R of a strip or wire.

> . . .

This is entirely a fictional scenario, although it's the one used by virtually all the currently available modeling programs. In those programs you can choose "free space" or "ground plane", where the infinite "ground plane" restricts the field, as Chris says, to a single hemisphere while "free space" allows radiation in both hemispheres.

In real life, you can't have either one, except that outer space would be a reasonable approximation of "free space". The only thing that matters is whether the field reflects from a large surface like the Earth on its way to the receiver. If it does, you potentially pick up field strength from reinforcement of the direct and reflected rays -- but of course you can also lose field strength if the two rays cancel rather than reinforcing. This is another way of describing the same phenomenon of increased gain due to a ground plane. Even if you put an antenna hundreds of wavelengths high, some of the signal will reflect from the ground -- it's not truly in "free space". It doesn't matter whether your antenna is a "ground plane" or a dipole -- if a reflection occurs between the transmitter and receiver, you potentially get that extra gain; if it doesn't, you don't.

> PA3DJS
> Please remove abc in case of PM.

I think I am missing something Wim. A slinky has a strip winding that
is edge wound which provides the largest disparity
between the inside radius and the outside radius. On one of the top
transmitters the inductance winding is such that the inner radius
is close to the outside radius. Naturally the different pitch of the
windings is very different as is the inter coil capacitance.
As Roy stated charges accumulate on sharp edges which I see as correct
but I cannot see how that alteres the diference all that much as the
same clearance is required So in the final analysis for less
inductance which form is which., the longer inductance or the shorter
inductance on the assumption that the number of turns are similara nd
I can acceptt your word for it? I referred to a slinky purely to
emphasize the importance of reverse windings so that lumped loadings
applied are cancelled. Actually the modern slinky is not contra wound
for some reason but I assume that is for the novelty movement reasons
for children and not because of radiation reasons. The slinky patent
is now defunct if that matters and iI am assuming that the fed would
be centre fed.
Thank you so much for responding
Best regards
Art

Ahah! Presently they don't. A big issue for opponents of 8VSB modulation
was poor performance in mobile/handheld (M/H) applications. Straight 8VSB
does not handle "dynamic multipath" well.

However ...

Development of the ATSC-M/H Standard for mobile
and handheld applications is moving forward at a
rapid pace. A critical element of that effort is the
Independent Demonstration of Viability (IDOV).
The goal of IDOV is to ensure that the technical
proposals under consideration can meet the goal
of enabling mobile and handheld services in early
2009.

per www.atsc.org/communications/newsletter/2007_december_standard.pdf -

I read some news accounts of supposed successful tests (the "IDOV" ?) this
past spring. We'll see.

BTW, alt.video.digital-tv newsgroup is doing a good job with the TV
transition. Also,
http://www.avsforum.com/ has news, like

OK, time to clarify...

Wifi (2.4 GHz). outdoor omni vertical (not whip), permanent mount on pole, to be connected (very short pigtail) to pole-mounted wifi router in client mode. Max output: 250 mW.

Is it true that the higher the gain the flatter the "donut" shape of the sensitivity field?

(And yes, my terminology is rudimentary... please forgive.)

why omni on a pole in "client mode" ?

If you are attemtping to connect to a specific Access Point,
this has been discussed here zillions of times,
and there are other questions, clarifications, and solutions available -
other than an omni -
Where are you in relation to the Access Point, how far, line of sight, etc

This requires a little different "thinking" than just putting up a bigger
stick
to talk to a 2m, 220, or 450 repeater -

I'm the one who initially committed than terminological crime so forgive ME! Where is that big omni gain going to come from if not from the vertical beamwidth? Start with the isotropic model pictured as a spherical balloon. Squeeze it however you want to. Nothing about an antenna can add volume to the model, its just a matter of how you squeeze it.

I have an A3S (a similar design). It sounds to me like either...
1) oxidized connection(s) between tubing section(s): disassemble, clean and reassemble tubing joints.
2) moisture inside a trap(s): remove trap(s), drain and "bake" the moisture out, and reinstall with drain holes pointing DOWN.
3) a bad 15m trap (actually resonant on 10m): replace if resonant frequency is not approximately 28 MHz.

That is the only way to get actual gain from a (horizontally)
omnidirectional antenna (excluding any MIMO designs).

Flattening the vertical radiation pastern may have severe drawbacks
especially if the mast is swinging in the wind or some weak (e.g.
indoors) users are close to the base of the mast.

Dunno about a program. I made a 2-turn transmitting loop for 160 one time, using a variation of Ted Hart's matching scheme. I did it by cutting it a bit long, then trimming it with an analyzer to see where it resonated. Eventually got it to 1:1 at about 1890khz where I wanted it and it received as well as could be expected. Transmit efficiency was on a par with a hamstick.

Thanks. I think you just explained the cause of a problem I fought in
about 1980. I had "designed" a 930MHz yagi antenna for a utility
telemetry system. In order to cut system costs, I decided to build
the antenna from stamped 0.062" aluminum. My initial dimensions were
stolen from a Scala yagi which used approximately 0.500" diameter
round rods for elements. I reasoned that to obtain the same
bandwidth, I would need to use the same circumference as the rod. That
made the initial prototypes elements 0.8" wide. After some tweaking,
the antenna tuned to the correct center frequency, but the 2:1 VSWR
bandwidth was much less than the original Scala antenna.

So, I increased the width of the stamped elements (with aluminum duct
tape) until the bandwidth improved. I landed at 1.25" or 2.5 times
the width of the rod elements, somewhat larger than the recommended
2.0 times the rod diameter.

However, when I added a coined stiffener groove to the stamped "boom"
and elements, the bandwidth increased again, to much more than
necessary. After the usual all night cut-n-try session, I landed on
2.0 times the width of the rod elements, with the coined stiffeners,
which apparently increased the effective diameter of the elements.

Coining the "boom" also wrecked all the element tuning since it
increases their effective end to end length by the depth of the
coining. I had a hell of a time dealing with the sheet metal vendor,

trying to control the stiffener dimensions. It seems that aluminum stretches when coined, often in a rather unpredictable manner. I eventually gave up and went to 0.125" sheet aluminum and no stiffeners. Unfortunately, only a handful of prototypes were made and shipped, so I have no clue as to how well (or badly) they worked in the field.

Of course, I meant to write 'equipotential' lines, but the doorbell rang at the moment I was typing that. 'Equipotent' sounds a bit like 'omnipotent', but in a shared manner (e.g. Greek gods)!

Reading the quotation again, even the '1/2-period later' seems incorrect. For the reactive part of the terminal impedance, the peaks or zero-crossings of current and voltage are separated in time by 1/4 of the period.

> Roy Lewallen, W7EL

Hello Roy,

You are right regarding non-uniformity, losses in the flat strip are
higher then based on the uniform current distribution (because of non-
uniformity). But this does not declassify loop antennas out of strip
material.

Based on a uniform current distribution (20cm wide strip versus two-turn loop from tube with D=2cm) one would expect heat loss reduction of 3.2. In my posting on Art's comment a mentioned heat loss reduction w.r.t. the 2-turn loop of factor 2.5 (to account for non-uniformity).

A strip (not near to other constructions) has effective diameter of half the width to have same characteristic impedance (as you mentioned). So a strip with physical circumference of 40cm (width = 20cm) has an effective circumference of 40*0.785=31.4cm. You need to have tube with D=10cm to have same effective circumference. I agree with you that this effective circumference is also a good starting point for calculation of AC loss resistance.

When Dloop is no longer large with respect to Dtube, current in the tube tends to take the shortest path, hence reducing effective diameter (and loop area) of the loop. In case of the strip, effective diameter (hence area) does not reduce. Radiation resistance is proportional to A^2 (for electrically small loops), hence Dloop^4. 10% reduction on loop diameter, gives 34% reduction of radiation resistance.

In my opinion, advantage of a strip is still significant with respect to a tube as long as you use a strip with width > 2*(tube diameter).

The FCC and the TV broadcasters looked the other way because there is no evidence that such activity has ever caused any interference. I can get 6 microphones to work in an occupied analog TV channel and neither notices the other.

The TV Band Devices the FCC has recently begun the process of authorizing are way more damaging than a 50 mW 65 kHz deviation FM signal.

Luckily, these devices will not be allowed anywhere near where I work. The FCC has banned them from the 13 biggest cities, and from within a kilometer of a venue or stadium using wireless microphones. The proposed rules do not require a Part 74 license for these protections.

bull!

>This eddy current has the units of
>current which somehow would match the
>description of the "weak force:".

eddy currents don't require weak force, nor displacement currents, they are
perfectly well described by existing magnetic field and conduction
equations.

>You stated previously that you wanted to know
>where the weak current equation is so, now you can start on a series

not me, i know where the weak 'force' is, and it has nothing to do with
electrical currents even though it is sometimes refered to as the
electro-weak force. that is a throwback to a VERY short time after the big
bang when the forces were merged, right now, unless you are experimenting
with a supercollider you can ignore the weak force as far as electric fields
are concerned.

>Stae equation you ask?
<handwaving bs snipped>

yes, state your equation that you 'derived'.

>Ofcourse you can declare antenna computer programs are in error and
>salvage your credability or place such a statement in the practicable
>book that you are writing! After all if it is printed in a book it
>must be right.......right?

but the computer programs that exist today, and DON'T use the weak force in anyway are perfectly in tune with maxwell's equations. and my book doesn't mention them at all, so don't hold your breath for that.

From "Electrical Communication", by Albert:

"Such a plot of voltage is usually referred to as a
voltage standing wave or as a *stationary wave*.
Neither of these terms is particularly descriptive
of the phenomenon. A plot of effective values of
voltage, appearing as in Fig. 6(e), *is not a wave*
in the usual sense."

From "College Physics", by Bueche and Hecht:

"These ... patterns are called *standing waves*, as
compared to the propagating waves considered above.
They might better not be called waves at all, since
they do not transport energy and momentum."

You must be older than I thought, you never are going to change.
Before you fade away
this last bit that you are now supporting regarding the weak force.
Can you account for every action
that reside in Maxwells laws including his addition? Can you state
that without doubt that eddy currents do not exist
during radiation? Or more importantly, that Maxwell's laws also omit
the presence of the eddy current?
Are you still of the opinion that radiation is a wave which implies a
string of connected energies instead of individual particle ejection?
Then pray tell me how exactly does the transmition of communication
eminate from a radiator and do a reverse action
in the transportation of intelligence? And then comes the biggy, How
does the Universe exist without being in equilibrium
a term you resist with abandon. Your knee jerk reactions to me are
starting to be absurd but as you are unemployed
you do not need now to answer to anybody regarding the thoughts of an
old man or concern yourself of the possibility of being fired.
Art

yes

>Can you state
>that without doubt that eddy currents do not exist
>during radiation? Or more importantly, that Maxwell's laws also omit
>the presence of the eddy current?

where did you ever get this idea. eddy current are currents in a conductor caused by exposure to an electromagnetic field. of course they are covered by maxwell's equations. you just have to use the proper boundry conditions and permeability/conductivity of the conductor to account for them. i have written software that modeled eddy currents from fields set up by power transformers, every equation was out of a standard text book.

>Are you still of the opinion that radiation is a wave which implies a
>string of connected energies instead of individual particle ejection?

yes, particle ejection, your magical levitating diamagnetic neutrino theory, is not necessary for electromagnetic propagation.

>Then pray tell me how exactly does the transmition of communication
>eminate from a radiator and do a reverse action
>in the transportation of intelligence?

energy my dear man, energy is conveyed by the electromagnetic waves and hence can carry intelligence... as opposed to what goes on between your ears, which must be quite a vaccuum.

> And then comes the biggy, How
>does the Universe exist without being in equilibrium
>a term you resist with abandon.

i abandoned equilibrium long ago. it is neither necessary nor desirable for any possible use of electromagnetic propagation that i want to make use of. if everything were in equilibrium the universe would be dead, it takes energy moving from here to there to make everything work. without flowing energy, hence non-equilibrium, nothing would exist... much like the space between your ears, maybe that is the problem, you brain has reached equilibrium with the outside world, hence nothing can flow in... though that doesn't explain the outpouring of bafflegab.

>Your knee jerk reactions to me are
>starting to be absurd but as you are unemployed
>you do not need now to answer to anybody regarding the thoughts of an
>old man or concern yourself of the possibility of being fired.

my reactions to your are pure humor. i love the pure illogic of your writings, reminds me of some old science fiction stuff by writers who didn't care if their proposals made any physical sense in this universe. perhaps that would be a good line of work for you art, you could write science fiction in the 'alternate universe' genre. maybe there you could come up with a story line that would make use of your distorted physics. and no, i am gainfully employed, someone has to contribute to the welfare system so you can collect your checks.

Well your background on this subject is far superior to mine so you
have the last word
and I must wander off to ponder my silly ideas. It was several years
ago that I brought up the subject
of pulses with respect to the tank circuit and the propersition that
current flows thru the center
of a radiator that was not in equilibrium. When you banish the idea of
equilibrium
I have nothing left to support what I say such that I have now reached
the Rubicon which
requires me to succumb to the teachings of books and abolishion of all
personal thought and reasoning.
Fortinately I am retired and thus cannot be fired or put to death on
account of my personal thoughts
so in my own little world I can still continue in what I am doing
except with regard to sharing or suggesting change
which on this group is a impenatrational barrier.
It was fun for a while but as I stated you have the last word.
Now await my next posting on a different subject!
Regards
Art

Art wrote:
"So now one must determine where the reflection occurs and science puports that it is not at the end of the antenna!"

Check your 1955 Terman opus. On page 887 is Fig. 23-24 showing current on a 1/4-wave antenna. Current discontinues at the tip.

On page 893 Terman says:
"An antenna can therefore be regarded as a resonant system with distributed constants. As a result, the impedance of an antenna behaves in much the same manner as does the impedance of a transmission line (see Sec. 4-7)."

Sec. (4-7) says on page 99:
"Similarly, with an open-circuited receiver, or with a resistance load greater than the characteristic impedance so that the voltage distribution of the open-circuit type (Fig.4-5),
the power factor is capacitive for lengths less than the distance to the first minimum. Thereafter, the power factor alternates between capacitive and inductive at intervals of a quarter wavelength, exactly as in the short-circuited case.

If Cecil were asked where a reflection occurs on an antenna or a transmission line, I`d wager he would reply, at the same place the impedance discontinuity occurs.

Art has asked similar questions several times. Art should answer some questions. What has his examination of Gauss` work produced that allows quicker, more precise or easier answers to the problems readily solved using Maxwell`s equations? What mistake has Art found in Maxwell`s equations?

Best regards, Richard Harrison, KB5WZI

==========
If your WiFi device is near the microwave oven , you indeed have a problem.
In my situation the oven is away (approx 7 - 8 metres) from the Wifi
system ,both router and laptop ,and I no longer had interference when
setting the WiFI System to the highest frequency (channel) with the
microwave oven freq at about 2390MHz.

Ouch. Maxwell works O,.KJ for me. I use computer programs based on
Maxwell. Gauss gave me pointers that Maxwell failed to do i.e he never
gave a true account of radiation
or explained the role of the weak force.Thus I have to solve these
things for myself or follow the other lemmings
What I do not understand is not his thinking but the interpretation
that others place on his thinking. It is this I challkenge.

For instance all the masters stipulated the condition of equilibrium.
Somehow those very same equationsapparently missed
the equilibrium content in their equations. Maxwell came along and
placed an addfition to their combined formular. So how come this was
concieved to be necessary and is this connected to a ommision of
equilibrium portion of there observations? So Richard that should be
considered as a
answer to a question. I then changed Gauss law of statics by changing
it to a dynamic field following the stipulation of equilibrium.
Maxwells laws via computor programs provided an array in equilibrium
so Maxwell has included everything in his equations.
Absolutely no problems there. It also provided by the inclusion of
equilibrium that a radiaoir can be comprised of many shapes which to
me brings the helix antenna into the subject. That to me is a answer
to a question as to how helix antennas enter the picture. All of this
point to management of the edict of equilibrium . Now I am confronted
by those who believe that current only flows on the surface of a
radiatorwhich clashes with equilibrium. Then it is disclosed that the
Maxwell addition was a current that did not provide a magnetic field!,
another clash that does not follow the equilibrium edict tho a tank
circuit used as an equivalent of a full wave radiator has no open
circuit which again clashes with the thinking of this group. I am
suggesting various alternative thinking to these aberations because
they just don;'t jive. I believe I am answering questioins as to why I
look for alternatives it is others that refuse to supply acceptable
answerts that marry with my questions.Now to the present problem.
Maxwells additive to the equations have the units of cuurent such that
Newtons laws are satisfied. Previous thought was it was a reflection
of the impact of the aether which has now fallen into disfavour
so what do we put in its place>? I gave that question to myself and
then provided effort to find a possible answer which I shared.
So Richard I am answering questions to the best of my ability which
includes explanations and not by clips uttered from booksthat are out
of date.
So you find it objectionable that I probe or challenge prior thinking
well.....write to physics departments and wilkipedia and demand
retraction of the recent statement made on behalf of the Physics
community but don't just blame me as it is your generation that have
provided the present mix up as to what radiation is comprised of by
hanging on to sky hooks
Art

Art wrote:
"Maxwell`s additive to the equations have the units of current such that Newton`s laws are satisfied."

Many experimenters wrapped wire around magnets hoping current would be produced in the wire. It never worked until Michael Faraday discovered that moving a magnet with respect to the wire or connecting and disonnecting a battery to a coil of wire induced a transient current in an adjacent coil.

Maxwell was a brilliant mathematician and theoretical physicist. He found he could formulate a set of equations which expressed all the known electromagnetic phenomena at once from all the earlier laws.

Maxwell noted his equations were similar to those which expressed the motion of waves on water. He was convinced that electromagnetic waves could exist and was able to calculate the speed at which they would travel.

To show that Maxwell`s equations actually represent wave equations, an equation is written in a form so that the magnetic vector potential varies in all three spatial directions and in addition, a source term (current density) is included.

If the source does not exist, we get a homogeneous wave equation for the magnetic vector potential.

Other potential functions or the various field variables themselves may be used to obtain similar wave equations.

Best regards, Richard Harrison, KB5WZI

"ml",.

I apologize if I offended you, but your comments were so poorly written that it was difficult to understand entirely just what you intended to say.

You suggested using the same methods used to preserve telephone poles. I discussed both the older methods as well as present day methods of wood preservation. Wood preservatives and sealers, such as creosote, pentachlorophenol, and chromated copper arsenate are far too toxic to use. But more importantly, they are also _very_ poor from an electrical standpoint in the _original_ application, i.e. for use on wood dowels as ladderline spreaders. I also clearly stated why boiling the wood dowels in paraffin wax, as done by oldtimers, did a better job electrically than than creosote. Previous posts I had written already covered the safety aspects of using hot paraffin, especially its flash point temperature., and the extreme danger of skin contact with the hot wax.

You then mentioned that _plastic_ is _a_ way to go. You did not mention which plastic as this is extremely important in the original application. Polyolefins (polyethylene, polypropylene) are extremely poor in outdoor use; they can fall apart quickly if exposed to bright sunlight. Polyamides (nylons) fare a little better but they too are soon damaged by the ultraviolet in sunlight. They are also damaged by acid rain. Polyoxymethylene (Delrin) is quite sensitive to halogens in acid rain. Polycarbonate and acrylonitrile-butadiene-styrene (ABS) plastics have good ultraviolet resistance only if stabilizers and absorbers are blended in; they have good chemical resistance to aqueous acids and bases, but they are quite prone to solvent attack. Polytetrafluorethylene (PTFE, Teflon) and other fluoropolymers have wonderful electrical properties (superb insulation resistance, low dielectric constant and loss tangent) as well as high ultraviolet and chemical resistance, but most are subject to cold flow and have poor temsile strength. In other posts I discussed acrylic and polyester plastics that are inexpensive, have good UV resistance and good electrical properties. I also discussed polyvinyl chloride and chlorinated polyvinyl chloride plastics. I didn't bother to consider polyimides (Kapton) as the cost would have been prohibitive. Suggesting "plastic" as you did without specifying which particular composition is essentially useless information. I gave my suggestions and the detailed reasons why I would pick certain plastics. I did not specifically mention cost except with the suggestion of plastic coathangers, but as an engineer.cost is an important consideration for virtually all my decisions. It was certainly a consideration for the original poster --why else would he ask about using wood?

Of the three methods of protecting wood in this application. as queried by the original poster, I plainly stated that urethane varnish would be my choice. I also explained why this would be preferred over shellac and paraffin wax. I further suggested which specific plastics would perform the best for the original application of transmission line spreader.

In the future, you should be far more clear in your writing if you really want people to take your suggestions seriously. You also need to be far more specific in your suggestions.

Again I apologize if I offended you, but I still stand by my earlier postings. If it bothers you, you can always filter out my posts. I certainly do this for a few of the people found here who espouse pseudoscience and refuse to defend their claims with either mathematics or experimental evidence.

Yes, I know there's nothing to gain in terms of performance. However,
I have very little space to work with. I have a 1 meter diameter loop
installed in my (tiny) attic that works very respectably on 10-30
meters. It won't get me onto 40 meters, though, and getting onto 40 is
either going to require a much larger diameter single-turn loop, a two-
turn loop, or a much more robust capacitor. Trying out a two-turn loop
seems like it would be the easiest and least expensive alternative,
and I already have the copper tubing I would need.

Two 1m dia turns will cover 40 with the same variable capacitor, I think
that is all you wanted to know!!! Experiment ...

I have need of a directional antenna for a 30 foot path within the house.
(the microwave oven wipes out the signal).

Do you have any better details on construction?

Guys! I've been selling these Biquads for a long time now and
everyone absolutely
loves them.
Check em out here... http://www.biquadantenna.com
Sold 30 just this month alone, and get emails all the time from
clients
on how good their performance is.
If it doesn't work, you get your money back! (minus shipping of
course)

Thanks for looking!
Pete

Yikes! I have never seen that. I would be concerned about leakage.
Sometimes I have torn into things and found stupid stuff like paint over
grounding surfaces or rust in the compartment. There is a critical ground
around the probe entrance.

My microwave oven is in the far corner of the house and I run 100 watts on
VHF and 600 on HF at times and never had trouble. I never tried the laptop
in the kitchen for fear of spillage. The Linksys is essentially on the
floor to keep people in the park next door from ripping up my bandwidth.
(although sometimes I would prefer geeks hanging out there to chase the rest
out) No coverage problems at all. I do have an HT that gets "some"
interference when I set it on top of the oven.

Yep, and if one impedance is infinite (or zero or purely
reactive), the magnitude of the reflection coefficient
is |1.0|, i.e. 100% reflection.

Ceci
If the surface of a conductor is completely covered by precharged
particles
and is aprouched by a changing electrical field would it not it be
opposed by the
electric field pre placed on the surface? Would the difference between
these two colliiding fields
create its own opposing magnetic field i9n concert with the main
applied electric field?
If we are to account for the electric field applied to the radiator
then we would have to add the energy
lost in the collision! After all the collision forces are no different
to the energy lost if the field produced
by the resting particles was the equivalent to a resister.
When Maxwell uses an "=:" that is an acknoweledgement of a state of
equilibrium such that the energy supplied to the radiator
must remain the same as the energy plus losses entailed in the closed
circuit and the collision created losses that must be accounted for.
Would it not be correct to say the applied energy must be equal toi
the primary electric field created plus the opposing electrical
field.?,
Ampere assumed that the energy applied to the circuit equaled the
energy received not knowing tha tthe energy would split into two
fields and not remain as one. This collision energy must be accounted
for on account of the addition of the "=' ancd the same energy that
Ampere was aware of but did not consider it to be present.(Note for a
discharged particle to have spin on ejection there must be two fields
present)
The bottom line is Ampere was correct with his law because he was
unaware that another field was present and thus did not include it.
Maxwell faced with combining all laws such that equilibrium occures
which allows the use of the "=" was left to account for it and thus

satisfy Newtons law.
Thus the eddy current fits neatly into the law of Maxwell and where the addition he made only became known at a later date by Foucaults discovery.
Thus the Foucault current or eddy current did three t things 1 it satisfied the laws of equilibrium ie "=" addition 2 he added an addition that matched the units and quantity values of the Foucault current in an exact form including the addition of the speed of light unit that reflects an implied speed of the ejected particle and 3 proved Einstein correct in his assumption that the Weak Force was part and parcel of radiation.
Now we see that the "interpretation" of Maxwells addition was in error or an invalid theory which can now be replaced by the eddy current addition
which concurrs with Amperes assertion that there are two ways an electric field can occur.
In summation the addition made by Maxwell was his mathematical intuition by stating that the energy applied equalled TWO electrical fields and not just one which was subsequently proven by Foucault.
Best regards

As I stated, I do not work for you!
I asked you to prove that the addition by Maxwell equaled the energy
lost
in the enablement of particle ejection, if you were capable. Obviously
you are not.
So I tackled it and lo and behold the jigsaw of radiation was
coimplete except for a single opening
and there was only one piece left. There was a drum roll and the place
was filled exactly by the addition oif the remaining piece.
The whole puzzle was turned over and there for all to see was a
complete piucture.
I addressed this to Cecil since he does not fool around and is
proficient in mathematics and stays in touch with his
Alma Mata. After all, if the jigsaw piece fits then you can;'t aquit

David and others, ham radio has always stated that we lead the field
in innovation
and public servie. What I have stated is a huge step forward in
science which solidifies our hobby.
Now we are at the point that all hams join the band wagon or place
hurdles to halt the advance
which puts into question the need for their existance. There are
plenty of people in the world that are quite clever
and work in academics. Some people in this world consider ham radio as
just a bunch of CB ers like KB9.......
and others who post on this group. If as I think I am correct in my
analysis you may be still alive to answer for your silliness.
Many others can continue to deny change and they will probably move on
to the next worlkd because of their age before change comes along
and probably "rest in peace". But you and some others could well have
an epitaph on your grave based on the history of this newsgroup
that" here lies an obstructionist to change in life but succumbed to
it in death.":

David, you represent the teachings of your professor of some 50 years
ago.
He is probably dead now and replaced in academia by people who
represent the best in science of to day
Thus you and many others have a disparity in science knowledge because
you stopped the regimen of continuos study and opted for the
pursuit of money. Naturaly those who maintained their inquisitiveness
and stayed attached to education circles will leave you behind in
education
where you would gain by attaining riches. Eventually you will be
replaced by those who do not dwell in the past that are younger and up
to date.
This is just a fact of life that happens every day in industry as the
recognition that experiences that are repetitive are just that, a
single experience, which is trumped by an open mind withouty
experience that is a fit in the modern world.

I think there's some confusion there about polarisation. VP requires lowest height to achieve a peak at zero degrees elevation; HP requires a frequency-specific height and low height usually results in an elevated beam.

From: ve2pid <ve2pid@videotron.ca>
Message-ID: <66e9aa1e-ad1c-4dc8-b324-99f96f4f286c@j39g2000yqn.googlegroups.com>
Source record: 19900

Hi to all

In a document from Roy Lewallen, we read this:

When a balanced antenna is fed with coaxial cable (Fig.1),
the outside of the shield appears as an extra, separate
conductor connected to the right side of the antenna at the
feed point. (page 157. What They Do And How They Do lt)

My question is this: Can we say the same thing for a dummy load (i.e
can we replace the words 'balanced antenna' with 'dummy load'?) so the
dummy load would 'see' three conductors?

We are trying to explain why some dummy load/Tx line systems radiate.
Perhaps, tthe current outside the coax (common mode current) exits,
while being very small, so the radiation could come from a leaking
coax... ?

Thanks de Pierre VE2PID

The laptop computer is downstairs about 10 feet from the microwave, and the
wireless router is upstairs about 30 feet away with a desktop(and the path
goes through three walls and the floor. The microwave doesn't wipe out the
laptop, but slows things down a bit. A directional antenna would solve the
problem. I'm not trying to increase range at all.

Fixed. I was feeling guilty so I ran it through the optimizer in
4NEC2. I haven't built a 5 dipole AMOS yet using these dimensions.

But a v-pol monopole up to 5/8-wavelength in electrical height, and mounted with its base near the earth _always_ launches its maximum relative field at zero degrees elevation (the horizontal plane) -- regardless of the quality of the r-f ground it uses, its operating frequency, or earth conductivity at the antenna site.

Radiation launched at low elevation angles by such a monopole is progressively less than in the horizontal plane. But its h-plane radiation (especially), and its low-angle radiation as launched are nowhere nearly as poor as shown in a NEC-2 analysis for these values over real earth -- which is what leads to the erroneous conclusions of many people.

The reason for this is that a NEC-2 analysis over a "real" earth is based on the field surviving at an infinite distance from the monopole, and over over a flat earth, at that !

But if that was the true radiation envelope of the elevation pattern actually launched by that monopole, then daytime AM broadcasting would be impossible (reality check).

The real-world, h-plane field intensity measurements made in 1937 from such v-pol monopoles at 3/10 of a mile over real earth of poor conductivity by Brown, Lewis & Epstein of RCA showed peak fields that were within a few percent of the theoretical maximum possible for monopole heights of about 45 through 90 degrees.

That's _Baluns: What They Do and How They Do It_, in the _ARRL Antenna Compendium_, Vol. 1, and also at http://eznec.com/Amateur/Articles/Baluns.pdf.

> My question is this: Can we say the same thing for a dummy load (i.e
> can we replace the words 'balanced antenna' with 'dummy load'?) so the
> dummy load would 'see' three conductors?

Not if it's a good dummy load. A good dummy load is shielded so that all the current from the center conductor stays on the inside of the shield. This current then returns on the inside of the coax shield.

> We are trying to explain why some dummy load/Tx line systems radiate.
> Perhaps, tthe current outside the coax (common mode current) exits,
> while being very small, so the radiation could come from a leaking
> coax... ?

Ok, let's look at a poorly designed dummy load, say a 50 ohm resistor connected with pig tails to the coax feedline. Remember that the current on the outside of the inner conductor is *always* equal and opposite in phase to the current on the inside of the outer conductor. Let's call that current I1. So the lead connected from the coax center conductor to the resistor has I1 flowing. If the pigtails are very short with respect to a wavelength, the current in the whole coax - pigtail - resistor - pigtail - coax loop is essentially the same, I1. So where the other pigtail connects to the coax shield, it carries I1 which all has to flow on the inside of the shield (so that the current on the inside of the shield equals the current on the center conductor).

But a dummy load radiating 10 uW, say, would drive a nearby receiver bonkers. If you put 100 watts into the dummy load, that means only 1/10,000,000 of the applied power has to radiate, and this can be hard to prevent. The pigtail - resistor - pigtail loop length isn't exactly zero, so there will be a little difference in the current at one end than the other. And this difference current will end up on the outside of the coax shield. In addition, there's probably some small amount of

coupling from the resistor and pigtails to ground, the feedline, and other conductive objects. This will result in a displacement current that causes current imbalance and consequent current flow on the outside of the feedline. The only way to prevent this is to completely shield the dummy load and transition to the feedline, and have no seams, holes, or cracks which could let any current get from the inside to the outside.

I've had limited experience with leaky coax, but have found a substantial difference between single and double shielded cable in the amount of signal radiated. Connector assembly is also critical -- it has to be done just right, or you'll end up with one of those sneak paths from the inside to the outside, regardless of how good the shield is. You usually won't have to deal with this, though, unless you need a pretty high value of attenuation.

Roy Lewallen, W7EL

Hi Pierre:
There can be several reasons for a dummy load radiating a signal but common mode current is not likely to be one of them. In a good dummy load the load resistor is inside a shielded container. If the container is RF tight the RF current is on the inside of the box and not on the outside, just like a coax transmission line all the signal of interest is on the inside surface of the shield and the surface of the center conductor. Skin effect works on shield boxes too. There should be little to no RF current flowing on the outside of container or the coax shield. One place the radiation could come from is from the coax itself. The shielding on typical coax is 95% coverage. This is a source of leakage. Connectors are a problem too. Pl259's are not a very RF tight connector. Type N's are better but there are some that are even better. Hard line is 100% shielded it would not be likely to radiate but it can be spoiled by sloppy connector installation. The most likely reason for any radiation is poor shielding of the dummy load. Typical ham grade dummy loads are not very well shielded. Often when using a dummy load and one finds that a signal is being radiated it easy to blame the dummy load when in fact it's the transmitter. Transmitters are not often all that RF tight. The only way to tell is to probe around with a field strength meter and find were the signal is coming from. This rambles all over the place, hope it makes some sense to you.

I put one up I use with a WiFi repeater and I can see dozens of
wirless routers in my neighborhood. The antena i mounted at about
20ft on my chimney. There are about 8 or 9 with no security. If I so
chose I would never have to pay for internet service. There is another
subdivsion behind my house I havent even looked at that one yet.
Strange thing I know 3 of the people who have the open systems and
they are farly savy about these things. I wonder if they are leaving
them open on purpose.

Jimmie

If the dummy load is effectively screened, and to the extent that it is effectively screened, there is very little current coupled to the outside surface of the outer conductor. That is very different to the feedline of an antenna which usually has significant mutual coupling to the nominal radiator.

>
> We are trying to explain why some dummy load/Tx line systems radiate.

The through braid loss (ie from inside of outer conductor to outside of outer conductor) is not infinite, so there is some leakage and it depends on cable construction and frequency. There is also leakage from the dummy load enclosure, transmitter enclosure, and other interfaces to the transmitter (eg power cable).

4686. Light, waves or particles

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-24 05:04:24 UTC
From: Art Unwin <ArthurUnwin@gmail.com>
Message-ID: <e6169735-b8d7-460d-84fd-a699408d7bb5@v15g2000yqn.googlegroups.com>
Source record: 19909

When Maxwell added the displacement addition it was
to place radiation in a system of equilibrium as the formulas did not
prior to the addition meet Newtons law of equilibrium.,
The addition of Maxwell to Amperes law in reality because of the
required units, was seen to be a force or vector that displaced
something
of which they did not know. It was later interpretation that the
displacement referred to the Aether
and from then speculation built up. Einstein saw this addition as a
very weak force and spent his life looking for the
characteristics and action of this force but failed and instead turned
to to relatavistic observations which led to
various important developments. In actuality this displacement vector
was Newtons reaction vector to the applied current which was later
confirmed by the discovery by Foucault and termed eddy current. It was
this applied current and its reaction force that applied a elevation
or anti gravity force and at the same time applied a spin component to
the residing particles on the surface of the radiator. So scientists
were correct in assuming that the weak force was a derivative of the
magnetic force but made an error in referring to this force providing
a
projective wave into the aether. Tho this theory of action has now
lost favor with the scientific community the idea
that light was a function of a wave took place and survived. With the
explanation that displacement current is the eddy current which
provides elevation together with a twisting action of the particle so
a straight line projection is enabled it thus destroys the notion of
light being a series of waves to being a series of particles in motion
with a
revolving movement. The basis of the above was determined initially by
changing Gaussian law of statics to a dynamic field by the addition of
radiators to the static particles while maintaining a state of
equilibrium such that it met the essence of Maxwells law's which then
led to a true desciption of the action of the displacement force
applied to particles plus providing further evidence for the Grand
Uniform Theory
Food for thought

I had a cheap samsung (I think that was it) microwave, it did slow
internet ...

I now have a 1.2 KW GE ... it does not ...

However, a leakage meter did show leakage from the samsung, and barely
reads on GE I have now, and I mean I touch the microwaves case to get
that reading!

So, what is the point? Buyer beware, with lack of consumer protection,
I would check the microwave myself rather than trust others to safeguard
me ...

To cut to the chase, and past the BS ... with the best affordable dummy load and solid coax, I can still chat a block down the street, at least (with decent power.)

Now, how this is occurring? Is it "leakage" from the xmitter onto the ac lines? Coupling to metal objects in the shack? Etc.?

Gawd only knows ... nothing is perfect ... when you find an answer to this mystery, please post back here; I am positive many more than me have wondered the same as you ... :-)

Oh gawd, I hate to get into these mud brawls BUT...
The regs were quoted a couple of messages back and it says - exerpted:
1. 50 watts ERP
2. And defines a dipole as shall be considered 0 dBd for the purposes of this regulation in defining ERP (as opposed to the usual 6.14 dBi over average ground)...

Now, typical of anything the feds define, it will be unintelligible... It is clear to me that the intent was to define the dipole as having a power gain of 1 (one) for the purposes of defining what constitutes 50 ERP when driven with 50 watts...

So, one might assume that it means that 50 watts into a dipole is considered 50 ERP - but it does not say that,,, It says for regulatory purposes that the power gain of a dipole is considered to be ZERO...

Which means - as I my math teacher proved - that 50 X 0 = 0 - per the regulation...
Given that the regs define the output of a dipole on 60 meters to be 0 ERP you can run 50 watts into any antenna with a power gain of 50 OVER A DIPOLE to meet the maximum allowed ERP... (which is why lawyers make a living)

denny - k8do

No it does not!!!

It says that the gain is zero *dB*, to convert from dB to a linear quantity,
which you can multiply, you must divide by 10 and then take the antilog.

So 0/10 = 0,
and antilog 0 = 1

So your sum is actually 50 X 1 = 50, not 50 X 0 = 0

It is much easier if you work in dB where you just have to add or subtract.
50W = 17dBW
so 17dBW plus a gain of 0dB = 17dBW

John
Academia does not accept studies from outside the club. The same goes
for the IEE and the IEEE
and ofcourse QST,radcom and the like. The internet is full of stories
where certain institutions have basically censored free speech for
years an action that is now continually exposed because of the
available of the Internet .I know it wears on the nerves on people
when I keep on hammering the point home= but it does find a place in
the record
But a long time ago this group stated that they would put down all old
wives tales. Problem was that many then took on the mantle of a pseudo
experts

which led to strong and petty auguments to real experts who passed by and never stayed for long. So I took them on without backing down when I had control of the facts knowing full well eventually they would be seenj for what they really are by those passing by. I think that now I have beat the naysayers into the ground where the facts provided cannot be defeated unless existing laws were mangled in the effort. Everybody on this group should now have a full understanding of what my investigation provided whether they believe it or not or like it or not. Nobody pointed out any conflict with present day laws which they would have jumped on if they were aware of them so I am now satisfied I have achieved my object of showing to all their true colours so basically I am done.
At the moment I am finishing up a new antenna of some 20 foot long with a dish reflector in the hope of attaining a rifle shot type of directive antenna.
Since my tower at the moment is limited to a 30 foot height I will be looking more at 20 M rather than the top band even tho it will be operable on that band
I am also adding with the hope it will work, an automatic tuning system as part of the antenna which will really push things to the limit. Scaled optimized computor studies show that the antenna has good gain but it is very difficult to narrow the beam width on more than a few frequencies which I am sure the closeness to ground will cloud the issue.
Best regards
Art Unwin...KB9MZ.......xg (uk)

It would certainly be best to remove the interference. If you have 4 bars
now, 5 bars might not do away with the problem. Moving the microwave just
5' more might be enough. You may have to bite the bullet and put in some
wiring to move the router.

Some of these guys are prone to take a practical problem like yours and turn
it into a full-blown engineering problem or a swap meet for their break
through technology or even an opportunity to throw mud. One engineering
problem we faced was how to contain UHF security and housekeeping repeaters
to a high rise building and it's underground structure. The final result
was 99% coverage in the building and the parking structure, but when
security went off the property, the radios went away. Visits to other
buildings showed no coverage there either. We had to do that for both
security and so we could get co-ordinated for licensing in an urban area.
But it was a multi-million dollar system. This is free.

Placing one of those in an upstairs room is an invitation to the neighbors.
I run a combination of wired and wireless. Wired to the desktop and to a

port replicator for the laptop and wireless to a print server with several printers in a shop area, and the AP is off unless I want to roam around or do print jobs. There are times I have printed from the laptop, wireless in the shop to baby-sit print jobs, but it keeps the office clear and quiet. One of these days I will have to run a cat5 out to the shop. It is simply faster and more secure. The end result is my router, 1 foot off the floor with the power set to 50% to do all I need to do.

Perhaps they want to take the blame for everyone downloading bootleg porn,
music and movies until their ISP terminates or throttles them for abuse.
Either that or they are trying to log mac addresses of those who do.

If stealing internet service from the neighbors is your intended
purpose, you selected the wrong type of antenna. A sector antenna may
be a great idea for running a WISP or central access point, where
you're never sure of the direction the client radios are coming from.
It's a bad idea for use at the client end. The idea is to pickup as
little interference as possible. You're reception of 9 stations is a
problem as any one of these could provide sufficient interference to
make your pirated internet connection useless. I suggest you look
into a panel or dish antenna, which will provide a much narrower
horizontal beamwidth, with the added bonus of more antenna gain.

>Strange thing I know 3 of the people who have the open systems and
>they are farly savy about these things. I wonder if they are leaving
>them open on purpose.

I was running an open access point at my office for a while. However,
I was also monitoring connection attempts and traffic. I figured that
nobody would bother. Wrong. I had some bum in a pickup truck and
camper, connect regularly to make VoIP phone calls. I had no problem
with him using the system and we eventually came to an arrangement.
However, he stupidly told all his friends, who immediately abused the
system, so I locked it up with a WPA password.

In another incident, one of my customers was in a hotel that wanted
real money to use their Wi-Fi. (This was about 6 years ago, before

the widespread proliferation of free Wi-Fi service). So, he connected to a random open access point. The security on his laptop was more than a little lacking (writable shared folders), resulting in the installation of multiple trojan horses, spam bots, etc. I suspect the open access point was an intentional trap set for hotel visitors.

Fb Roy and thanks (to all) for the explanations.

But... returning to your document, I wonder why a balanced antenna
'see' that third wire, but the dummy load does not recognize that
third conductor. Is it because the common-mode current outside of the
shield has something to do with a kind of RF coupling?

Just noticed I spelled that wrong, "honeypot" ...

Yes, well, I take it for granted, anyone able to set up and run a
honeypot will also have the wits to manage it correctly ... but, ya'
never know, ya' just never know.

Best exercise is to trace-route them and report them to their, proper,
ISPs ...

I'd say stealing is bit strong, I run an open wireless access point
here, its' SSID is "WelcomeAboard!"

I think that "wrong type" (referring to OMNI, apparently) of antenna is
perfect, given there are a few access points within range. You can
"bridge" multiple access points for better throughput ...

Current doesn't flow one way or another because the path is "seen" or "recognized". It has to obey Kirchoff's Current Law, which it might be useful to review. It states that the (vector) sum of currents into or out of any node must equal zero. In this case, the node of interest is the connection of the dummy load to the coax shield, which is effectively the connection of three conductors: the conductor to the dummy load, the inside of the coax shield, and the outside of the coax shield. If the current on the inside of the shield equals the current to the dummy load, the current on the outside shield equals zero per Kerchoff. And this is what happens if the currents in the two dummy load leads are equal and opposite in phase. Similarly, if the current to the two halves of a dipole are equal and opposite in phase, the current on the outside of the coax is zero, and conversely. The whole article is based on that principle, and explains how it can be accomplished.

Please look at Fig. 1, and the currents going to each side of the dipole. If the two coax conductors go to opposite sides of a resistor rather than to two sides of a dipole, those currents have to be equal or nearly equal, as I explained in my last posting. If they are equal, there is no extra current available to go along the outside of the coax.

You asked about RF coupling. I explained in my last posting that coupling to various objects could cause the currents in the two dummy load wires to be unequal, resulting in current on the outside of the coax.

Sorry, I'm running out of ways to explain this. You might try reading the other responses if you still don't understand.

My home system is "1540 Jackson Ave" which is my address. The
assumption is that someone wanting to use my system can bang on the
door and ask permission. My office SSID uses the company name.

>I think that "wrong type" (referring to OMNI, apparently) of antenna is
>perfect, given there are a few access points within range.

I'll stand by my statement. Unless you're running a mesh network, an
omni at the client end is a bad idea. The client knows the direction
of the desired access point and should use a directional antenna to
minimize interference. In my limited experience (I ran a small WISP
and neighborhood LAN/WLAN for a few years) interference is the most
serious impediment to reliable operation. The more you can do to NOT
hear the undesired stations, the more reliable the connection.

>You can
>"bridge" multiple access points for better throughput ...

Sorta. You can do route switching easily enough, but load balancing
between multiple internet connections can't be done without IP
bonding, which requires everyone's cooperation (including the ISP's).
The problem is that you can't use multiple ISP's to improve the
download speed from a single connection. For example, if you want to
download a large file, it will only go as fast as the speed of the
fastest ISP connection. The other WAN interfaces remain comatose
because there's no way to bond the single destination IP to two
different download streams and routes. You can download something
else using the 2nd WAN interface, but you can't use it to increase the
speed of the first. Uploading has a similar limitation, where you
can't improve the speed to a single connection. Where such routers
work best is if there is a LAN full of users sharing multiple WAN
connections, not for a single user looking for "better throughput..."

I've used a few of these with moderate success:
<http://www.edimax.com/en/produce_list.php?pl1_id=3&pl2_id=>
(See load balancing and multi-homing routers near bottom of page).

Incidentally, multiple cient radios, run to a passive combiner in a single omni antenna is a total loser. The FCC specifically proscribes synchronizing wi-fi radios. Even if the isolation can be increased sufficiently to prevent receiver overload, it's highly probable that a receive packet will arrive exactly when some other client radio goes into transmit. Some relief can be obtained by using different non-overlapping channels (1, 6, 11), but only with expensive bandpass cavity filters. The spread spectrum spreads quite nicely into the spectrum of the adjacent radio.

>> However, you can't compensate for this factor when the ground is poor by improving the ground system. The reason is that the reflection takes place much farther from the antenna than nearly any ground system extends. And low angle radiation, where the improvement is most needed, reflects the greatest distance away.
> __________
>
> Roy, didn't the experiments of Brown, Lewis & Epstein of RCA in ~1937 show that the h-plane field measured 3/10 mile from a vertical monopole of about 60 to 88 degrees in height, over a set of 113 buried radials each 0.41 WL, was within several percent of the theoretical maximum for the applied power as radiated by a perfect monopole over a perfect ground plane? And conductivity at the NJ test site was poor -- 4 mS/m or less.
>
> That tends to show that the fields radiated at very low elevation angles also will be close to their theoretical values when measured at this radial distance, even though ground conductivity at the antenna site is poor. The relative field (E/Emax) for radiators of these heights and propagation paths approximately equals the cosine of the elevation angle.

I believe we've discussed this before, so I'll be brief.

Their calculation of the field at the receiving site when the radial system is perfect was adjusted for the effect of ground wave attenuation caused by the imperfect ground conductivity. If the ground between the antenna and receiving site were perfect, the field strength would have been greater.

Also, I'm speaking of sky wave. Ground reflection isn't a factor in determining surface wave, which is what they measured and which isn't of interest to most amateurs.

> The greatest radiated fields always will be directed in or near the horizontal plane when measured/calculated for such conditions. This also will be true for any monopole from infinitesimal to 5/8 wavelength in height, although the elevation pattern of monopoles from /4- to 5/8-WL no longer are described by the cosine function (see http://i62.photobucket.com/albums/h85/rfry-100/MWElPatComparison.jpg).
>
> Elevation patterns show maximum relative field centered at various elevation angles above the horizon, when those fields are measured at progressively longer radial distances from the monopole, due to the propagation loss for the surface wave over other than a perfect, flat, infinite ground for those ranges. Earth curvature and terrain diffraction add to those losses for longer surface wave paths over real earth, and for very great distances the h-plane relative fields falls to ~zero.

As I thought you were aware, the surface wave propagates considerably differently than the sky wave.

> But that pattern shape is not the pattern shape originally radiated by the monopole, it also includes the effects of the propagation environment at the range where it was measured (or calculated).
>
> If this were not true then MW broadcast stations would have essentially zero coverage area for their groundwave signals.

It would be a mistake to design HF antenna systems based on optimizing surface wave propagation as AM broadcasters do, unless you desire communication for distances not exceeding a few miles.

> The above is an understandable conclusion using NEC analysis, however it is not supported empirically. If it was, AM broadcast stations would perform very much differently than they do.

NEC analysis has been supported many times by measurement and observation.

> The measured data in Brown, Lewis & Epstein's 1937 benchmark paper "Ground Systems as a Factor in Antenna Efficiency" proved that the *radiated* groundwave field from a vertical monopole working against 113 buried radials each 0.41 lambda in length was within a few percent of its calculated peak value for a radiation pattern with maximum gain in

the horizontal plane. The path length for the measurement was 0.3 miles, which was in the far field of the vertical monopole configurations measured.

Yes. The question is what is the calculated value. B, L, and E normalized their measurements to the unattenuated field strength at one mile for 1000 watts radiated power. I couldn't find anywhere in their paper where they explained how they determined the ground attenuation between the antenna and their observation point.

> BL&E's measurements, and the results of thousands of measurements made of the groundwave fields of MW broadcast stations using such radial ground systems ever since demonstrate that their peak gain always lies in the horizontal plane.

No, the field strength is strongest at low elevation angles only close to the antenna, as you further explain below.

> It is true that, as a groundwave propagation path becomes longer, the field measured at increasing elevations above the earth at distant ranges might be higher than measured at ground level at those ranges. But that is not because more field was launched by the original radiator toward those higher elevations -- it is because the the groundwave path has higher losses, which accumulate as that path lengthens. Therefore a NEC plot showing the conditions reported in the quote above do not accurately depict the elevation pattern as it is launched from the radiator, and the groundwave field it will generate.

Of course the standard far field analysis doesn't accurately depict the field close to the antenna -- it's a plot of the field at points very distant from the antenna, as clearly explained in the manual. NEC allows you to include the surface wave if you want, and it accurately shows the total field including the surface wave at a distance of your choice. (Accurate, that is, up to a hundred km or so, beyond which the deviation of the flat ground model from the curved Earth begins affecting results.)

Don't feel bad -- Reg has a lot of trouble understanding this, too.

> There are software programs designed for calculating MW groundwave field strength given the FCC "efficiency" of the radiator and the conductivity of the path. The radiator efficiency is the groundwave field developed by the radiator with a given applied power at a given distance (1 kW @ 1 km). These values must meet a certain minimum level for the class of station. I think in all cases, they must be within ~0.5 dB of the theoretical value for a radiation pattern with its peak gain in the horizontal plane. In the case of directional MW antennas, this performance must be proven by field measurements.
>
> Finally, standard equations show a peak field of ~137.6 mV/m at 1 mile from a 1/2-wave dipole radiating 1 kW in free space. The calculated groundwave field at 1 mile radiated by 1 kW from a 1/4-wave vertical MW monopole over a perfect ground plane is ~195 mV/m. This is the same field as generated by the free space 1/2-wave dipole, when all

radiation is confined to one hemisphere (137.6 x 1.414).
>
> The groundwave fields measured from thousands of installed MW broadcast antenna systems confirm that their intrinsic radiation patterns are within a fraction of a decibel of that perfect radiator over a perfect ground plane, no matter what is the conductivity at the antenna site (N.B. Reg).

No, the measured fields from quarter wave broadcast antennas are considerably less than 195 mV/m for 1 kW at one mile, unless perhaps there's only salt water between the antenna and measurement point. As you explained above, the surface wave is attenuated with distance. What you seem to be missing is that the attenuation is strongly dependent on ground conductivity (between antenna and measurement point, not just at the antenna site) and frequency, so the actual field strength at one mile for 1 kW radiated will always be considerably less than the perfect ground case. The 195 mV/m and associated values for various antenna heights is the "unattenuated" or "inverse" field, which doesn't include the surface wave attenuation beyond simple inverse distance field strength reduction. It's the field strength you'd get if the ground between antenna and measurement point were perfect, not what you get over real ground. I'm not very conversant with FCC antenna measurement methodology, but somewhere the measured field strength is normalized to the unattenuated field strength by fitting to a ground attenuation curve, which in turn depends on frequency and ground conductivity. (I've been told that this is the way broadcasters determine ground conductivity -- by seeing how far the measured field strength deviates from the unattenuated value.) I believe that the surface wave attenuation curves used by the FCC are from the 1937 I.R.E. paper by K.A. Norton. That paper is also the basis for NEC's surface wave calculations.

interesting paper..

The big benefit (from a cursory reading).. is that you have a more consistent antenna pattern over the frequency range, which the vanilla bowtie does not. And a somewhat wider match bandwidth. (mostly extending it to higher frequencies)

Nothing magic, though.

The charged particles (electrons) are the carriers of the
RF wave. The negative charge of the electrons seems to matter
little in the generation and sustaining of RF EM photonic waves
since photons are generally assumed to possess neutral charge.
However:

From PhysicsWeb News: "A physicist in the US has analyzed radio waves
from distant galaxies to obtain a new upper bound on the electrical
charge of the photon. Brett Altschul of Indiana University has found
that the charge is no more than 10^-46 times the charge of the electron
ï¿½ assuming the existence of photons with positive and negative charges.
This is 13 orders of magnitude better than the previous direct bound on
the charge of a particle that we normally assume to be neutral".

Probably because the dummy load is a resistor not referenced
to ground. The antenna feedpoint impedance is a resistance
referenced to ground, i.e. not a resistor. The "third wire"
is also referenced to ground. You might consider it as a
kind of RF ground loop.

There is apparently a "big benefit" for some applications
contrary to the nay-sayers on this newsgroup. Apparently,
the self-symmetry of fractals leads to some predictability
as far as wide-band response goes.

> Nothing magic, though.

Don't remember anyone saying that fractals were magic. They
certainly obey Maxwell's laws. I suspect their advantages,
like their straight-wire cousins, lie in the predictability
of their mathematical models.

As opposed to randomly trying other shapes, I guess..

So fractals fit in the "handy design approach" category

I dare say the Yea-sayers cannot predict any specific, practical,
fractal characteristic when given fractal
>mathematical models.

For the inverse (starting with the practical instead of the
mathematical model) one very simple test:
give the mathematical model for a single fractal
antenna specifically resonant on each frequency:
1.85MHz;
3.8MHz;
7.15MHz;
10.13MHz;
14.15MHz;
18.11MHz;
21.2MHz;
24.93MHz;
28.5MHz,
to within the margins of any Ham band represented by the single
frequency offered.

Solution:
Biconical;
LPDA
(barring, of course, no one can give the fractal mathematical models).
Of course, the joke here is that these are neither very gainful, nor
small - the presumed boon of fractal invention. Yet no other
"fractal" can describe this antenna above. Those "fractals" that come
close (maybe covering 3 of the 9 bands) aren't small or gainful
either. Sometimes you just can't win for trying either.

Going to specifics, what is the mathematical model (not just a word
salad description) for a Sierpinksi Gasket? Using that mathematical
model (what students call plug-n-chug for solving an equation), show
the free space best gain at its sixth iteration, fourth resonance (the
30M band of the description above).

What is the greatest physical dimension of this 9 band antenna? What
would be its greatest physical dimension if implemented in a fourth
iteration Triadic Cantor (if, in fact, one were possible to support

these resonances)?

So, a specific fractal antenna, a specific implementation, a specific characteristic - and years before anyone here will offer a demonstration of -dare I say it?- predictability. Hasn't happened from any other correspondents here to this board in the entire history of the topic. In that same history, not one other scribbler has offered a link to someone who can do their work for them.

Fractals, always amusing.

Fractal design may prove as good of a way of shrinking an antenna as
any other. Its just pure BS to think it is going to let you make a
smaller antenna with the same gain as the full size antenna it was
derived from. It is Mega BS to think that you are going to shrink the
antenna and achive gain because of anything the fractals will
contribute.

I separated this out from the noise floor......

When I was dealing with a loop, I wanted to extend the frequency downwards - it's a pretty big loop, but trying to hit 75 meters was a goal, I had some exchanges with Reg, and he pretty much told me to put a extra capacitor across the terminals so I could tune it to the lower frequency. That was a smack the forehead moment for me.

And Oh yes, tuning will be soooooooo tight. But the cap will probably be better than an extra loop. You'll just have to figure out how to switch it in and out of the circuit.

Cecil, we badly need a definition for a wave. I see a wave as a series
of a bound electron structure versus the unbound
particle but then everybody has different ideas such that bound
particles or electron move within the surface of matter.
You could even see water as a bevy of particles impinging on the
miniscus such that separate impacts oprovides an occillatory movement
onel It would Also appear that some see linear movent occures in
matter and it is this carries a wave. Until the definitions are made
clear
hams will be in their element as the arguements will have no end in
sight. What is certain because of disagreement where the displacement
vector is and what i8t acts upon some have to rethink their stance on
radiation for the next generation who are susceptable to change. As
for the others they can move on to the next life comfortable in their
long held positions will prevail for ever. Seems like we have
offricers that are screaming at the troops that their hats
or berets are not straight while ignoring the bedlum created as the
enemy passes thu the lines!
Thanks for responding

Best regards
Art

Is a unsecured wifi AP more like putting some benches on the sidewalk in
front of your house or a house with an unlocked front door?

This would a good example where the "law" isn't settled.

Unlike the door example, where there is millenia of houses and doorways
to establish a fairly common understanding of boundaries and permissions
required (and even then, it varies among places, right?)

To a first order, if you own one endpoint of the link (i.e the AP), then
you get to look at what its carrying. Unless you're a "common carrier"
or "utility" sort of organization.

And how far does YOUR liability extend, if, say, that miscreant out
front is using your AP to organize a terrorist plot? ISPs have a "safe
harbor": if they don't look at the content, they're not responsible.

Or, does having that open AP give you plausible deniability, and the
SODDI (Some other dude did it) defense... Hey man, it wasn't me
downloading copyrighted music to that IP, it must have been some other
dude with a laptop in a car out front. Bummer that I don't have any
traffic logs.

Hi Mike,

More the achievement would be finding the capacitor that could carry
the current.

Did you follow through with this frequency extension of your loop?

Since fractal antennas are finding practical applications
when etched on a PC board, your discussion is about as
moot at a 160m rotatable Yagi proving that rotatable Yagis
are not feasible.

As far as the FCC is concerned, I suspect that the usual "third party reception" rules would apply. If the communication is transmitted over the airwaves but is not intended for you, you're permitted to intercept the communication but *not* to make gainful personal use of what you overhear.

There was one company which tried to prosecute some local "wardrivers" who had publicized the fact that the company was running an open wireless network. The FCC not only refused to pursue their complaint (pointing out that the company had created the problem and failed to mitigate it by turning on WEP), but cited the company for running an illegal Part 15 network (they were using external high-power amplifiers on their APs).

I'm reasonably sure that any criminal actions you implement with the use of such data (e.g. making any unauthorized access to a protected computer system, etc.) would *NOT* seen as legitimate by The Powers That Be, even if you gained knowledge of that data by scarfing it off of your own access point during an unauthorized use thereof.

As I understand it, there isn't any standard interpretation (even in under U.S. laws) as to what rights-of-usage apply to an open access point, in the absence of a statement by the AP's owner as to what the rules are. The FCC doesn't appear to consider this aspect of the wireless problem to be part of their jurisdiction.

I believe that in some areas, using such an AP without having received some explicit form of permission is considered to be a tort (a civil wrong) and the owner could file suit against you. Using the AP to break into a computer network (e.g. accessing files, etc.) could easily qualify as a prosecutable "computer crime".

I've read that some municipalities have passed a rule which says that the act of setting up an insecure access point, and broadcasting beacons "to the wind", counts as something akin to an open invitation... enough so that the use of the AP without explicit permission isn't considered a crime, or (I think) even a tort. This might especially be true in the case of those APs/routers which come with a WEP password pre-installed (the 2Wire models are one example) and in which the owner must explicitly disable the security feature if s/he decides that this is appropriate.

LMAO! My SSID is the same as my front gate Password. That way I never have to worry about opening it when I get home from work and the party is always in full swing when I get there! It's a little bit bothersome when dead bodies turn up in the moat though!

Lo and behold, here is one http://tinyurl.com/665r5a but it's a throw-back to a simpler time when the HP42S calculator was an engineer's prized tool. If you have a 42S, punch it in and use it. Otherwise, this is mainly a learning tool to show how simple the calculations are. I think this design could be put onto a Lotus123 calculating spread sheet where all the output data windows would suddenly by filled up upon entering the needed input data.

Nope. Two wrongs don't make a right. You'll also find that "an eye
for an eye" and retailiation are not actionable in the USA legal
system. Simply having your rights violated, does not magically make
it open season on the perpetrator. The courts are expected to deal
out the necessary justice, not you. For example, catching a burglar
in the act does not give you the right to pound him into the ground.
You can and probably will be charged with battery for doing that.

I have some experience and opinions with Wi-Fi related crimes and
enforcement, but I don't wanna start yet another political discussion.

I'm really disappointed in the comcast customer's website - - I tried to access the program later in the evening and found it required I sign in - - even though I specified the file to be "public". Let me know if you have trouble getting the file. I would appreciate any recommendation for a better way to access the Word document than the use of this comcast facility.

Proximity effect isn't a factor unless conductors are very close together -- I suggest you review the previous postings which explain it. As far as "better", the answer is that it probably doesn't matter, since either a wire or strap can usually be pretty easily made large enough to make loss negligible in those applications.

Digital is a major step toward "conditional access".

Proximity effect is when you are too close to a directional microphone
and the bass is accentuated. I think you mean mutual coupling.

So is analog. If you don't have the proper reciever, you can't pick it up.
Just a different format.

Wrong one of the several meanings, Dave. See fourth entry under
http://en.wikipedia.org/wiki/Proximity_effect.

A good example of such a dummy load is the Bird Termaline
Coaxial Resistor. I've got model 8020.

Many of us have checked the net for the latest advances in antennas.
Advances are usually arrived at public university research units some
of which are partially funded by outside sources Most, if not all,
the results are presented to the IEEE as a way of getting recognision.
But this information such as advancement in science is not provided to
the public even tho they came from a public institution. Thus you
cannot access it on the net as a member of the public as access is
with held UNLESS
you hand over some money to the IEEE. Why are the universites not
sharing their work with the public?
Is it because academics feel they are part of a special club divorced
from the public? Ofcourse I may be wrong
in taking that view in light of the fact that these study results are
available in libraries but why are they not put on the web for the
good of science and the general public at large?

I dont steal internet service but I do have an arrangement with a
couple of my neighbors so we can use each other service.
This has come in handy a couple of time now in just the last few
months when my cable went out and another neighbors cable modem went
out.
Its also a ton of fun just to build the antennas and be able to do it.

I must confess I have tapped in to a few unsecure home APs to check my
email while traveling. These are often easier to find than a hotspot.

All the above, N connectors and double shield coax. RG8X types seem to be the worst for radiation, although it does have other redeeming features. I take it you have RF in the shack even on the dummy? Don't forget about other RF paths like the audio shields and data lines. Regular 95% shielded coax is said to have isolation of about 60 dB (RG8, 58c) maybe as much as 90 dB for double shielded. Unless there is some bump in the line that causes the shield to radiate. There will be resonances in the entire line that cause points of high voltage and high current.

This is a complex issue and one of considerable debate within those universities AND the publishers of the journals.

1) The journals have operating costs (someone has to edit them and do the typesetting and production).. these must be paid by subscription fees and page charges from the author. Giving it away for free means that other means must be developed for funding.

2) Not all the funding for research comes with a "must release to public" clause. For instance, you might get a grant to defray part of the cost of some research, and fund the remaining part out of your own assets. The granting agency gets the data they want (at a lower cost than paying for all of it), but you retain the rights.

3) Putting stuff on the web isn't free.

However, a LOT of newer research IS being published for free on the web. PLOS (Public Library of Science), PubMed, arxiv, etc. are all examples.

Remember, too, that this is academia, and they tend to be conservative and change slowly. To a certain extent, it IS an exclusive club, because publication leads to promotion, and the publication process is full of gates and wickets. The term "publish or perish" did not arise out of thin air.

Why is it that the general public rejects anything beyond sound bites and
clever slogans?
Why is it that some experts completely reject mainstream thought and even go
so far as to present their own paradigm complete with their own private
semantics and definitions. Not many actually learned the Klingon language,
although many were accustomed to hearing it on TV. Like Psychology and
Philosophy where every major school of thought had it's own paradigm,
language, definitions and required intimate study as if it were a cult unto
itself. The end result was many led astray by loony professors who had
dreamed everything up in their heads and sought to prove it by changing all
the rules. Even Charley Manson still has his followers. Oh to be sure
there had to be some element that rang true - some brain prick of insight to
trigger the euphoria to forge ahead. But nearly all found their theories
held true only for a few specimens they held under their own microscope.

What's your point, Art? Are you looking for a grant to start your own
school of Philosophy?

Why don't you get a web presence where you can put your lab notes, math and
drawings. You can copyright them unless they belong to someone else.

And the 80 year old method of modulation, a combination of pulse, FM,
and analog was just as much a restriction to specialized equipment. If
you tried to get TV on your XTAL radio, it would be like listening to
an encrypted secure network.

If you stood out in a field and tried to listen to AM radio waves
(without even the boon of that XTAL radio), you would still suffer
"conditional access."

So, what is the big deal?

Well said !
It pleases me that it is a subject of debate. If the publishing is
part of the business
then ofcourse the market decides whether it is read or not. One would
have thought that public universities would
also publish the benefits of their work for all and thus advertise the
high standards of the university.
From a ham radio point of view we have the ARRL organization but the
do not seem interested in advances in the science
even tho they have the vehicle (QST) to keep its members up to date.
But it is not the private institutions that I point the finger at but
the public institutions
who now take on a mantle of private business by forcing students to
buy high price text books where their is a feed back to them or
increasing tuition costs that doesn';t seem to marry with the present
market but yet are paid for by public funds. I suppose that the
present state of affairs will continue if academia doesn't peruse the
web or publish their thesis even tho they actually belong to the
institution. In the mean time I am happy to make a over 100 mile round
trip to a suitable library to spend a day reading on the premises as I
am not allowed to visit Roswell.
Thanks for your input
Regards
Art

4754. FS Brand New Hy-Gain Tailtwister Rotor

I have for sale a brand new Telex Hy-Gain T-2X (Tailtwister) rotor. It comes complete in the original box and has never been used. The rotator has never been out of the box except when I took it out to test it. It is the older version without the plugs for the control cable. It has the original manual and accessory packet and it comes with approximately 50 feet of new rotor cable. It lists new for $799.95, and I'll take $575 for it and the cable. See more specs at the Hy-Gain website at: http://www.hy-gain.com/Catergories.php?sec=8 Thanks, Charlie Hugg, K5MBX

Too late! I've already built the 4-bay bowtie:
http://www.youtube.com/watch?v=EWQhlmJTMzw

But I used ER70S-2 1/16 weld filler rod (stiffer than a coathanger, and
copper-plated; solders like a dream):
http://mysite.verizon.net/richgrise/images/QuadBowTie.jpg

And it works just spiffy! I had to go to Whittier Electronics to get
the balun, since RS seems to have dropped them from their line-up:
http://www.whittierelectronics.com/

It was $2.99; the rest of the antenna was free. :-)
(yes, I'm really that broke.)-;)

Thanks,
Rich

>in feb it will switch to digital however shall still be free

The current situation is somewhat analogous to what happened, decades ago, when television in the U.S. moved from VHF-only to VHF-plus-UHF.

Everybody who wanted to receive the full set of channels, had to either buy a new TV, or buy a UHF block converter so that they could downshift the UHF frequencies to a VHF frequency that their existing TV set could receive.

The television signal is, and will remain, free to receive (or, rather, its transmission is funded by advertising). There is no fee on the user to receive the TV signal.

The equipment needed to receive TV signals in the U.S. is not, and never has been free.

This is a somewhat bigger switch-over, technology-wise, than the expansion to UHF some years ago. Whether it's a Good Thing or a Bad Thing is, I think, much more of a personal conclusion than anything that can be decided objectively.

The length of coax doesn't matter. What matters is that
the antenna is 1.5WL on 40m and the series matching
section is 0.5WL on 40m. After that, what you get is
what you get.

A converter box can be had for about the same amount of cash as a cup
of coffee after using the coupon, so that arguement is moot.

What "rich fat white executives" do you think are getting enriched by
the switch since almost all the converter boxes are made in China?

Ideally, not if the SWR is 1:1 on the 50 ohm coax
in which case, the RMS voltage and current is constant.
Such a line is known as a "flat" line. At any point up
and down the line the ratio of voltage to current
is 50 ohms.

It sure hasn't taken long for the ability of some people to find information to contract to the single source of the Internet.

But other sources still exist as they have for a very long time. And IEEE publications are and always have been available to the public.

A lot of university libraries have IEEE publications which are available for free viewing. And I have yet to see a library that lacks a way of copying an article.

Even my humble local library, which lacks even a single decent EE text, is happy to get any article I specify via an "interlibrary loan". Not only can I get anything the IEEE has published, but papers from the most obscure journals as well.

OK. I don't have a big problem with folks using frequencies they're not assigned when there isn't an interference issue, although I also don't have a whole lot of sympathy for those same folks if one day they *are* interfered with by assigned users.

> The TV Band Devices the FCC has recently begun the process of authorizing

If these are consumer-type devices, realistically how will the FCC stop their use in those 13 cities? It'll be like GMRS where technically everyone's supposed to be licensed yet, in actuality, I imagine that well under 1% of the actual users are: If the consumer can buy a radio off-the-shop at Wal*Mart, there'll use it wherever they want, regardless of what FCC rules say.

You might want to look at QEX magazine. It's the ARRL technical
publication for experimenters:
<http://www.arrl.org/qex/>

Also, publication, free or otherwise, constitutes disclosure, which
has signifigant effects on the patent process. Premature public
disclosure can easily invalidate a patent. It must be done carefully,
with due consideration for the implications of publication. Here's a
short summary of the situation:
<http://uwadmnweb.uwyo.edu/rpc/InventionDisclosure.asp>

The ARRL's interest in advances in the sciences is intentionally
limited to their applications to amateur radio. While hams may have a
good general interest in scientific advances, the number that apply to
amateur radio is rather limited. I have specific opinions about some
of these advances, such as the ARRL's discovery of Wi-Fi:
<http://en.wikipedia.org/wiki/High_speed_multimedia>
but I don't have the time or strength for yet another endless debate.

In my never humble opinion, the ARRL's support and publication of ham
inspired new technology has been usually late, limited, and sometimes
wrong. (NBFM using commercial radios, FM repeaters, packet radio,
packet networks, computahs, etc)[1]. Fortunately, this has not always
been the case, as PSK31, bizarre antennas, satellite, and SDR have
been well supported and published. Personally, I would be quite happy
if the ARRL concentrates on what nobody else is doing, which is acting
as a lobbyist for amateur radio with the FCC and the government.

[1] I still recall articles in QST in the late 1960's and early 1970's
on how to convert commercial FM radios into AM radios. I often
wondered what the ARRL was thinking.

>from the universities! And every one of those "new designs" mentioned
>here were worth every penny I spent.

Out of curiosity, does that include the IEEE Transactions on Antennas
and Propagation and the IEEE Antenna and Propagation Magazine? I'm
currently debating the merits of re-joining the IEEE mostly to obtain
these publications. In the past, they were literally gold mines of
interesting ideas on antennas. However, like all gold mines, I had to
dig through a considerable amound of rubble and useless garbage to
find the gold. I've seen little of this stuff on university web
piles, except after publication by the IEEE. I drag myself up to UCSC
and borrow a few issues, but I prefer to have them online
(downloadable and searchable) which costs money.

Do I spend the money, or do I seach for your secret horde of free
university publications on antenna design?

Hmm that is interesting. Seems like the popular thinking is to resist change as everything is O.K.
EXCEPT fior the ARRL and CQ magazine. Can't really fault that tho I suspect that many would be better of saving their money
and use it to set up a personal business instead of spending it at university. Seems like the financial advantages of old with respect to return
has floated away in the wind. Why go to university if the older books like Termans and Jackson has everything that anybody wants to know and at a reasonable price compared to the price of books that Universities foist on their students?. Does the world really need advances in science and for whome?
Regards
Art

>I just put up a 160 G5RV antenna. Is 140 foot of 50 0hm coax required
>to make yhis antenna work?

I'm not sure what a "160 G5RV" is. This tells you all about the real
G5RV, written by the inventor himself:

http://www.gw0rtp.co.uk/antenna/g5rv/g5rv.php

And this shows how it performs:

http://antennagraphs.com/ne8r_G5RV.htm

You can use a G5RV on 160 by strapping the feeders to give you a Marconi
T-style antenna, but it's a pretty poor compromise.

> experience with one or more of them and can make a recommendation for one.

Higher gain omni has flatter /narrower beam. So it has to be pointed
more accurately, tilting as needed to connect with desired AP.

As Jeff says, there's no reason to use an omni for a client. Get a
much cheaper directional antenna and you will get more gain with less
interference. Pointing will be easier too.

Take a look at the pattern for this one:
http://pnt.zoovy.com/product/MD24-12/12dBi_24GHz_Mini_Directional_Antenna.html

Or consider a combination weatherproof box with built in panel antenna
like this: http://tinyurl.com/5kfd42
(Choose the version that has the pigtail you need)

That's the first thing you want to determine, by the way, how much
gain is needed? Another thread....

Funny story... I work as a contractor and was in an office in Louisiana that supposedly had an internal wi-fi setup. Signal sure did seem weak for an internal connection. All the guys there said they didn't know what happened to it. "It used to work good".

Mr. Boss, the guy who installed it originally, was in town and said "hey, whats wrong with the wifi?". Turns out the little wireless router had fallen behind some other gear and become unplugged. All during this time the office traffic had been going thru the network of a nearby residence.

A lot of universities have Transactions for most of the societies like A & P as well as the Proceedings. IEEE members get free access to online Proceedings and all past issues of Transactions for all societies they belong to. For example, if you're a member of Antennas and Propagation, you can access online any paper in any issue of the Transactions on Antennas & Propagation. The incremental cost for joining a society is modest -- A & P is $36.00 per year once you're an IEEE member. (I think you can get Trans. on A & P or others without joining, but at a much higher price.) I just renewed my membership and joined the Microwave Theory & Techniques Society for only an additional $14.00. Now I'll have online access to all the past Transactions for that group.

Incidentally, anyone can purchase and download any individual IEEE paper online for around $20. A lot of other organizations like the IEE (U.K.), physics societies, etc. have a similar offer. I've gone this route a number of times when it was worth it to me to avoid the hassle of going downtown to the university library or waiting for an interlibrary transfer.

If you're used to looking at A & P transactions from the '40s through the '60s, you'll probably be disappointed with current issues. Research has always concentrated on where the money is, and now it's coming from much different industries than it was a few decades ago. Samplings from the current issue: "Synthesized-Reference-Wave Holography for Determining Antenna Radiation Characteristics" and "Parallel In-Core and Out-of-Core Solution of Electrically Large Problems Using the RWG Basis Functions". No Brown, Lewis, and Epstein papers, those! But there was an interesting paper on putting RFID tags on explosive ordnance as a possible way to locate it when unexploded and buried, and a short paper on coax loss.

4778. A few questions about collinear coaxial antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2008-11-25 22:55:52 UTC
From: Thomas Magma <somewhere@overtherainbow.com>
Message-ID: <_n%Wk.13$zQ3.3@newsfe12.iad>
Source record: 19756

Hello,

I am about to attempt to build a UHF collinear coaxial antenna and am trying to finalize a design. I have done a lot of reading and am a little confused on a few things. First off I have read contradicting statements whether to use odd or even number of 1/2 wave elements. 1, 3, 5... or 1,2,4... Also I don't understand what the 1/4 wave whip is doing on the top without a ground plane (found in most designs), is this necessary for a receive antenna?.

Instead of using coaxial cable, I will be building the 1/2 wave and 1/4 wave transmission lines out of ridged copper pipe with air as it's dielectric in order to maximize the velocity of propagation and therefore making true 1/2 wave elements. Does anyone see anything wrong with this approach?

Thomas

Hi Jeff,

Surely you must realize that this is not about money (a convenient
foil in this troll topic), but about skill (what the troll lacks).

The cheesy inventions that we have been breathlessly advised of have
the commensurate value of the bandwidth they return in a simple Google
search. It takes very little effort to recognize the moldy
fluorescence surrounding those meager offerings.

If you want the exact article specified, yes you can shell out money.
If you want the research behind it, and probably more data than you
would care to wade through, you simply investigate the investigator.

Myself, if I don't want to spend any more than the cost of bus fare, I
go to the engineering library, check it out, bring it home, scan it,
and its done. As I am on campus twice a week anyway (and the cost of
bus fare is already covered for my other activities), it is hardly an
imposition and the university certainly isn't suppressing me as they
give alumni library privileges.

Even public libraries have online access to special topic databases
(subscriptions) - unless you live in Bumf**k, Illinois.

Now, if you happen to be a troll who visits a campus infrequently only
to spit on their library shelves, I can well imagine the ego-bruised
outrage that is visited upon us here after they give you the bum's
rush.

Required? You've been lined up against the wall for a shakedown so
you can watch TV? With porn free on the Internet, the only successful
economic model is they pay you to watch Digital TV for FREE! And they
DO!

I think Madison avenue would have those rich fat white executives
gutted (too slow to move anyway - are you talking about AIG or the
Paleolithic RNC?) before their hooves clattered halfway down the alley
you've been suckered into.

Hi Thomas

I think you can design and develop a very good colinear coaxial array at UHF using copper pipe. Do you have any requirement for VSWR? Do you have need for operating the antenna at other than one frequency? It isnt easy to develop a good UHF colinear without good test equipment. How will you measure input impedance? Do you care about the angle of the radiation pattern maximum? End fed colinears will have beam squint with frequency change.

Hi Jerry,

My application is at only one frequency so I intend to centre it on that frequency and the VSWR I get is the VSWR I get. I would hope to be > 25 dB return loss anyways. I do have a HP8714C network analyzer in the lab I will be using so that is no problem. Due to the centre frequency (lower 400 MHz) I figure I can only realistically have about 4 of the half wave elements because of height, weight and wind loading. Oh wait was that 3 or 4 or 5 elements. I still haven't solved that fundamental issue yet. I don't suppose

the radiation pattern is too much of a concern at this point, as long as it is omnidirectional.

Thomas

Frequency re-allocations were mentioned up the thread in
news:icqev5-8mc.ln1@radagast.org

I'm surprized no one has mentioned http://www.tvfool.com

Here's what you can expect to get in one part of Whittier
with a 20' mast:
http://www.tvfool.com/?option=com_wrapper&Itemid=29&q=id%3dea7348065e
(The results are a graphical representation of the data
so it's not searchable with a text search utility.) 8-(

Here's the version that isn't scrunched into the middle of the screen:
(Right-click; Show only this frame)
http://www.tvfool.com/modeling/?id=ea7348065e
(Your exact zip code and elevation may give different results.)

The lowest commercial channel you will get is the
faith-healer/preachy-movie channel reallocated from 40 to 23.

The *all will move below 52* statement in Platt's wasn't accurate.
While KDOC56 will move to 32, KLCS58 will move to 41,
and KOCE50 will move to 48,
KCOP13 will move to 66 and KCET28 will move to 59.

If you look for why something cannot be done, I believe it, you will find it ... if you look how to make something happen, you will, most likely succeed--given the time and investment of energy ...

Naysayers abound, this group is an excellent place to find them, I don't consider these people "assets." Frankly, I just ignore them and go on--you will choose what you wish ... all you have to do is decide on the path ... but then, something tells me you already have been told this, and not just once.

Absolutely, with public colleges and universities ... if they use public
funds, the knowledge is public. Perhaps, someday, a decent attorney
will take them to task. The college I hold a position with knows all of
this, we make as much as humanly possible available--we are educators
and we take our responsibility SERIOUSLY!!!

But, somehow the trash has gotten into the system ... :-(

Careful. The channels you mention as "will move" are already operating
digital
on the "will move to" channels. Some will stay where they are.

At Transition, the four LA stations on analog VHF-HI channels, 7, 9, 11 and
13, will secure their digital UHF transmitters and initiate digital
transmissions on their historic (analog) channels.

After Transition, no so-called "regular TV" will be on channels 52 and
above. Other services have won bids for those channels. Qualcomm has
channel 55 for MediFLO mobile TV, etc.

Pls see http://www.rabbitears.info/dtr.php and scroll downpage past New York
to Los Angeles (they're in market-size order). See the fourth, fifth and
sixth columns for each station's FCC assignments: analog, interim digital
and final digital. It's all there.

I hope this helps.

From modeling I did a long time ago: there is a slight advantage to
using high velocity factor line, but it's very marginal. Just as a
dipole doesn't need to be resonant to do a good job radiating (and
receiving), so the elements in the coaxial collinear don't need to be
resonant. The phasing among the elements is dictated by the coax
between the feedpoints. Each gap between two elements is a feedpoint;
across it is impressed the line voltage. Since each line segment is a
half wave long and the conductors are reversed at each junction, the
voltage across each feedpoint is the same and in phase, less a small
amount for line loss. The element currents depend on mutual coupling
among the elements, but my simulations for VF=0.66 to VF=1.00
indicated that the current phases were always very nearly the same.

Generally, you'll want all the elements to look the same from the
outside. The top element should be the same length as the rest. It's
common to short the coax an electrical quarter wave up from the
highest gap between elements; that reflects back an open circuit to
the bottom of the top element, so really you could just as well make
the top element a tube the same OD as the rest of the elements,
connected to the inner conductor of the next lower section. The
feedpoint impedance at the bottom of the antenna is just the parallel
combination of all the feedpoints, which are generally each fairly
high (since each one is feeding a full-wave doublet, essentially), but
with ten or so sections, the net is modest, generally around 100 ohms.

Whatever the feedpoint impedance is, you need to match to it properly--
to whatever degree of matching is "proper" in your book. I generally

use a simple "L" network: a variable C across the feedpoint, and an inductor to the feed line center conductor. It matches the impedance and can tune out some reactance. Then you need to decouple the antenna from the feedline, and from other metal in the area where it's mounted. I generally use self-resonant coils in the small feedline, one immediately below the antenna and one another quarter wave lower. You could also try sleeves or radials...

Summary: the coax provides proper feedpoint phasing (even if the elements are shorter than 1/2 wave because of the VF of the line used); a matching network lets you match to 50 ohms (or other impedance if you want); decoupling keeps "antenna" current off the feedline.

Cheers,
Tom

Hi Thomas

If you can use whatever frequency the antenna works best at, it may be practical to build one then use the frequency of best performance with that antenna. But, if you have some predetermined frequency that the antenna must perform well at, there is a problem building prototypes. It can get rather time consuming to build prototypes when using copper pipe. Aparently you are confident that you can evaluate the antenna's input impedance. I had figured that would be a fairly difficult task.

I'll be very interested in this project. Please keep the group informed of your progress.

Jerry KD6JDJ (who has designed similar antennas for commercial use)

Not the versions of NEC used by most amateurs.

Those versions show zero or very low gain in/near the horizontal plane
for a
vertical monopole over real earth. This leads to the common (mis)
belief
that those are the gains of the radiation pattern _originally
generated_
by the monopole.

But that belief is untrue.

Each TVBD will be addressable and can be shut off when it consults the
database. The top 13 cities thing is probably an oversight, but it's in
the proposed law.

The proposed power for a portable device is 100 mW, except on a
first-adjacent to a DTV station, which is 40 mW. This makes no sense
because the 2nd adjacent channel is more likely to interfere.

Excellent post. The problem with QEX is not enough submissions. As for the QST AM mods, I was thinking that was ATV, but maybe you were talking about something else. The same applies to QST. If there aren't enough submissions, the only recourse is to hire writers to do columns or fill the empiness with drivel and ads like 73. The best things to come out of 73 was the Star Trek communicator clone and Byte magazine. I hate how Ham Radio magazine died out. I was President of the local ham club for a while, and wound up doing the newletter too. For the three or four years of that, I only got 3 submissions from the membership. All the rest I had to either pull out of my A** every month or go around like a reporter and interrogate people.

On the other hand - What neat inventions can we come up with to share with the World, so it can be exploited and give reason to take more of our spectrum? Interesting to note how public safety volunteers showed Los Angeles Sheriff how neat ATV was and they turned around and petitioned the FCC for those frequencies.

Oh well, we will probably all be shot in head by the next regime because we are an irritation.

>A lot of universities have Transactions for most of the societies like A
>& P as well as the Proceedings. IEEE members get free access to online
>Proceedings and all past issues of Transactions for all societies they
>belong to.

It's the ability to search and download proceedings, reports, and
articles that interest me. I do that now at the local multiversity
(UCSC) but there are problems. However, there are problems. Since
I'm not an alumnus, teacher, or employee, the annual cost is about 1/3
of an IEEE membership plus 2 IEEE society memberships. In addition,
some items of interest are not available off campus. The local
library has access, but that requires a pilgrimage to the library
every time I want something. As long as my reading requirements were
minimal, a few trips to the library or paying for individual papers
was cheaper than IEEE membership.

The current economics are:
IEEE membership: $169/yr
A & P membership: $24/yr
I couldn't find the current costs of the various printed transactions
and magazines. My guess is at least $40/yr.
With only downloaded issues, that's about $200/yr or $17/month. I
value my working time at about $75/hr. If joining saves me 3 hours of
time, it's break even. That's about how much time I waste on just one
trip to the local university, so I guess membership is justified.
<http://www.ieee.org/web/membership/Cost/dues.html>

<http://www.ict.csiro.au/aps/>
<http://ieeexplore.ieee.org/xpl/RecentIssue.jsp?punumber=8>

What go my attention and inspired my questions was the alleged free availability of antenna design articles from various secret university archives. I've found a few, but nothing compared to the online IEEE A&P collection.

>For example, if you're a member of Antennas and Propagation,
>you can access online any paper in any issue of the Transactions on
>Antennas & Propagation. The incremental cost for joining a society is
>modest -- A & P is $36.00 per year once you're an IEEE member. (I think

I haven't checked the current numbers but last time I checked, the annual subscription price was exactly the same as joining the IEEE. I'm sure that was planned.

>I just renewed my membership and joined the Microwave
>Theory & Techniques Society for only an additional $14.00. Now I'll have
>online access to all the past Transactions for that group.

Hmmm.... I hadn't heard of that group. So many groups, no little time.

>Incidentally, anyone can purchase and download any individual IEEE paper
>online for around $20. A lot of other organizations like the IEE (U.K.),
>physics societies, etc. have a similar offer. I've gone this route a
>number of times when it was worth it to me to avoid the hassle of going
>downtown to the university library or waiting for an interlibrary transfer.

I'd forgotten about the wait, which requires two trips to the library. I ordered several articles from the local library. Apparently, it's a common thing, costs nothing, and is fairly simple. All the articles and abstracts are easily searchable on the IEEE web pile, so obtaining the necessary identification was trivial. What I didn't expect was that to save the library some money, they only ordered such transfers on Tuesdays and only delivered perhaps a week later. There was no charge for hard copy, but an extra charge for having it delivered on a CDROM, which methinks seems backwards. This was about 2 years ago, and I haven't done it since.

>If you're used to looking at A & P transactions from the '40s through

>Functions". No Brown, Lewis, and Epstein papers, those! But there was an
>interesting paper on putting RFID tags on explosive ordnance as a
>possible way to locate it when unexploded and buried, and a short paper

>on coax loss.

Sigh. Such esoteric and obscure research pays the bills and feeds the
academics, but also adds considerable clutter. My areas of interest
is probably considered equally narrow and arcane. With a suitable
search engine and filter, I can live with it.

Actually, the current issue doesn't look that horrible:
<http://ieeexplore.ieee.org/xpl/tocresult.jsp?isYear=2008&isnumber=4685873&Submit32=Go+To+
Issue>
For example "Internal Coupled-Fed Shorted Monopole Antenna for
GSM850/900/1800/1900/UMTS Operation in the Laptop Computer" appears to
genuinely useful.

Incidentally, there are "delayed" RFID tags of sorts, that use long
term chemical action on the chip or PCB, to activate its operation
after a pre-determined interval. Basically, the chip arrives shorted,
and the short disappears over time. The logic is that RFID can be
used to locate unexploded mines and ordinance after the battle or war
is finished, but not during the action.

Thanks much...

If I had money and the necessary skills, I wouldn't be asking dumb
questions in this newsgroup.

>The cheesy inventions that we have been breathlessly advised of have
>the commensurate value of the bandwidth they return in a simple Google
>search. It takes very little effort to recognize the moldy
>fluorescence surrounding those meager offerings.

Wrong. Techno-hype became somewhat of a hobby of mine. During the
dot.com boom of the late 1990's, I was deriving considerable income
from doing technical sanity checks on business plans and projects.
During this time, I accumulated a fair collection of patents and ideas
that are pure bogus, yet were successfully promoted at least to the
point of being funded by technically clueless investors. Many are
still around today. Considering extent of the problem, and the fair
number of bogus patents, I would suggest that it is NOT easy to
recognize technical quackery.

>If you want the exact article specified, yes you can shell out money.
>If you want the research behind it, and probably more data than you
>would care to wade through, you simply investigate the investigator.

I've been shelling out the money. I just want to shell out less
money. Your suggestion that there was some secret horde of free
research articles on antenna research at universities caught my
attention. I guess not.

>Myself, if I don't want to spend any more than the cost of bus fare, I

>give alumni library privileges.

I haven't been on a bus in perhaps 25 years. The local multiversity
(UCSC) is on top of a mountain. I like to bicycle but at my age, the
hill is a challenge. Parking is impossible, expensive, or both. I'm
not an alumni, but am tempted to take exactly one class just to become
one. I've been "borrowing" accounts, but that has it's limitations.

>Even public libraries have online access to special topic databases
>(subscriptions) - unless you live in Bumf**k, Illinois.

Thanks, but I've tried that. See my other rant in this thread.

>Tom

Thanks Tom for the detailed explanation. My current sketch of my antenna design uses a quarter wave sleeve on the lower end of the antenna to stub the current off the feedline ground. I am hoping to see the antenna having a (somewhat) characteristic impedance of 50 ohms since the transmission elements although made out of copper pipe and copper rod are designed to be 50 ohm and the antenna is single end fed (unlike a dipole). I will make some provisions for a small tuning structure. If I do have to tune, the nice thing is that it will be a receive only antenna and I can get away with small RF components.

Tom, since you seem to know quite a bit about collinear coaxial antenna design, do you know if I should be using an even or odd amount of half wave elements? I planned on four, do you see a problem with this.

Thanks again,
Thomas

What design? Drawing? Description? NEC model? Numbers?
UHF is about 300 to 1000MHz. Any particular frequency?

Incidentally, it's not a "coaxial antenna". It's an end fed vertical
colinear using coaxial cable elements.

>First off I have read contradicting statements whether to
>use odd or even number of 1/2 wave elements. 1, 3, 5... or 1,2,4... Also I

>wave elements. Does anyone see anything wrong with this approach?

Yep, lots wrong. End fed colinear antennas are convenient but far
from ideal. They're also deceptively simple where the problems only
show up after the antenna is built.

1. Most of the RF comes out the bottom of the antenna. Very roughly,
the first dipole belches 1/2 the RF, the next dipole belches 1/4 the
RF, then 1/8th, and so on. This is NOT exact, but close enough to
illustrate the problem. You can make it as long as you want, but if
somehow manage to cover up the lower part of the antenna (a common
problem on a rooftop or side mounted on a tower), most of the signal
is history.

2. The alternating 1/2 wave coax cable type antenna is twice as long
as necessary. Every other 1/2 wave coax section is essentially a
non-radiationg phasing section. That's convenient for construction,
but not very compact. A similar antenna, using a simple 1/2 wave
hairping stub, with be half the length, with the same gain.

3. Coax is lossy. Coax phasing sections add un-necessary loss that
is not present in an antenna that uses (for example) a hairpin stub or
coil instead. Your copper pipe and air dielectric idea eliminates
this problem, but I thought I would throw this in for those building
them from coax cable scraps.

4. End fed antennas tend to have pattern uptilt. That may or may not be a problem depending on your unspecified application. The uptilt doesn't show up on free space models, but is certainly there if you include the effects of a rooftop, ground, or mast arm. If this is going on a mountain top, you might consider mounting it upside down.

You can reduce the uptilt problem somewhat by cutting the antenna in half and feeding it in the middle (forming a dipole), rather than end feeding it. Several commercial antennas work this way. That also eliminates the need for ground plane radials at the base.

5. The effects of the radome can be critical. I built such a UHF antenna for 463MHz long ago. It worked well enough with exposed sections. However, when I potted it with urathane fence post foam in a PVC pipe enclosure, the center frequency drifted downward sufficiently to render the antenna useless.

6. Cutting the coax sections accurately is difficult. If you're not using a fixture for cutting, forget it.

7. Making it out of copper pipe is rather expensive but certainly possible. Making the insulators will be somewhat of a challenge. There's no velocity factor involved (Air=1) so the measurements will be simple. However, since there's an overlap between sections, I'm wondering from where to where you should measure. If you cut the outer copper tubing to exactly 1/2 wave, then you need a very thin insulator between sections to prevent shorts. Methinks there will need to be some cut-n-try along with some careful measurments (swept VSWR) along the way.

Good luck.

Esoteric? As an issue of loss, it is probably more common than
conductor shape, and is (unlike most of the scribblings here to this
group) decidedly on-topic and focused.

Hi Jerry,

It is a predetermined frequency that I am building the antenna for. It is not determined if it will become a commercial product yet but I am trying to design it as such. I can see that it might be a little time consuming working with copper pipe, but once I get the formula right I should be good to go. I'll start buy calculating the half wave elements based on theory knowing my dielectric constant will be dry air or Argon.

The design I have sketch is pretty neat and clean (on paper anyways). It has all the elements stacked directly on top of each other, unlike the traditional staggered approach you see in other designs. Also the dielectric chamber of the transmission elements are sealed and can be filled with a

noble gas such as Argon to prevent corrosion and detuning from humidity.

My background is in receiver and transmitter design, so I'm quite familiar with impedance matching and I understand how a Smith chart works on a network analyzer.

I'm looking forward to working with copper pipe instead of 0201 capacitors and a microscope!

Roy and others have answered this one in the past too. You employ the
near field table to observe the ground wave. It works approximately
well, even out to the edge of the implicit flat universe. If you
object to flat universes, you are no longer in the realm of ground
wave. If anything, modelers give MORE response in comparison to the
BL&T data.

I'm not aware of such a widely held misconception, but it is indeed untrue.

You must have conducted some sort of survey to find out what "version" of NEC-2 is used by most amateurs, you know more than I do about it. Although there are a few minor variations of NEC-2, there's not enough difference to justify characterizing them as different "versions". And every one I've seen has the capability of producing data which include the surface wave. It's done with a simple entry on the RP "card".

A number of different compilations of NEC-2, every one of which as far as I know which includes ground wave analysis, can be had at http://www.si-list.net/swindex.html. You can also get the manual there, where you can learn about how to get the ground wave data from it. You're obviously much more interested in ground wave field strengths than most amateurs, so I suggest that you download one of the free NEC-2 compilations, and the manual, and them for your investigations. Remember, it's done with the RP "card".

With EZNEC, you have to use the near field analysis to include the ground wave; direct ground wave analysis isn't included in EZNEC because it's of very limited use to most amateurs. In fact, it's really of interest only to AM broadcasters and a very few other very small and specialized users, who just about universally use EZNEC Pro which does include direct ground wave analysis.

But anybody who's interested in direct ground wave analysis can also use one of the other modeling programs which includes it, or use NEC-2 itself, available free from http://www.si-list.net/swindex.html. The manual is available there also. NEC-2 produces field strength data including the ground wave if requested with the proper entry on the RP "card".

Sure it IS easy. Unfortunately, there are plenty enough people who have
Mad Skillz in the suspension of disbelief.

Looking at technical guano and judging it as such is not difficult.
There are ways that dilettantes or the intelligent uninformed can detect
the aroma of hi-tech manure.

In a field where I am mostly ignorant - finance -I called shenanigans
when I first heard of heard of the new breed of ATM's. I yelled fraud
when I heard of the sub prime loans, and shook my head in disbelief as
80 year old people took out 50 year mortgages that folded interest and
principle back into the loan. And yet while I knew the present economic
crisis was coming back around 2003, it seems a whole lot of people
couldn't see that. And I was told by enough of them that my "old school"

view of economics was surely evidence of my stupidity.

In science, economics and technology, the evidence is all there, the fundamentals are still quite serviceable, and analysis is not difficult. The problem is that people start out with a basic premise such as "Owning a house is the American Dream", or "The old guard is saying that all is already known about antennas", and then trying to fit everything into *that* philosophical Iron Maiden.

So I can take a look at say Art's antenna, and draw the conclusion that it is very likely an inductor on the end of a pole, and it will tend to perform like an EH antenna, with the coax serving as the major radiator. Contacts can certainly be made. I don't even condemn it out of hand, I don't think it is anything new, and after looking at it, it just seemed to be a lot more effort to build than I wanted to trouble myself with.

Yet I'm an uneducated dilettante dummy - most people out there are a lot smarter than me, so how come they can't figure this out when I can?

Hi Thomas

Your plan for this colinear antenna appears to be identical to the one I designed for ACI in Van Nuys Calif.. It was stack of lingths of copper tubes with no stagger. I dont remember what I finally did nor how it was assembled. I do remember that it worked and that my supervisor was impressed. Also, I remember that alot of impedance measurements were performed.
I am sure you will get your antenna to work. I suspect you will get more familiar with that Smith Chart in the process.

There are outfits that make Omni Antennas for the 2.4 Ghz Band, that
have Down-tilt designed into them. This helps deal with the flattening
of the Vertical Polarization for local connections. I have one located
on a 60ft Tower that has multiple AP's at various Azimuths, with ranges
out to 2 miles. Works well for a Central Distribution.

Hi Jeff,

Thanks for all the good points, but you haven't scared me away yet:) My
target frequency is around lets say 418MHz (that's not really it, I like to

remain anonymous). It was interesting what you said about the radome and how it detuned the antenna. Do you think it was mainly the PVC or the urethane foam that caused the issue. I plan to use a fibreglass tubing and spacers so hopefully I don't see as much near field effects as you did. I have learned that some PVC pipes have certain conductive additives and are not so good for antenna use, plus it might be tough trying to sell a 'poop pipe' antenna commercially if it ever became a product of ours.

Do you happen to know if I should be using a odd or even number of half wave elements in my design? I'm beginning to think it doesn't really matter.

Thomas

A couple comments:

First, about the feedpoint impedance. With four elements (a rather short antenna at UHF), there are three gaps between elements, that represent three feedpoints. Each feedpoint directly couples to the two attached elements, and through mutual coupling to the other elements. Consider driving just two such elements: it's just a (nominally) full wave doublet, and the feedpoint impedance is pretty high. Large diameter elements drop the feedpoint impedance, but even with large (not "huge") elements, the impedance of such a doublet will be several hundred ohms. To a rough approximation, in the coaxial collinear, you are simply putting three of those in parallel, since you're connecting them through 1/2 wave (electrical length) coax. If the feedpoint is just a half wave (electrical length) of coax away from the bottom gap between elements, you'll see the same impedance echoed there. In ten element designs, I typically see around 100 ohms at that bottom antenna feed spot. I fully expect to see quite a bit higher than that with only four elements. You can simulate this pretty easily with a program like EZNEC: just make a structure with four elements, with equal voltage sources between each pair of elements; figure the parallel combination of the reported impedances at each feedpoint, and that will be a good estimate of the impedance you'll see any even number of half-waves of feedline removed from the antenna, assuming negligible loss in the feedline.

Second, about number of elements: it really doesn't matter a whole lot. It will affect the impedance you see at the feedpoint, but the antenna gain should go up monotonically with the number of elements, if you get the phasing right and decouple the antenna from its surroundings appropriately.

(Beware sleeve decoupling: it may not be as effective as you think...)

I learned about these antennas when I got pissed that I could never seem to make one work right when I followed the instructions given in the old ARRL pubs. I finally sat down with pen and paper and EZNEC and worked out what was really going on. One thing I learned was that the "magic" of the wax fill in the Stationmaster commercial antennas wasn't really magic; neither the line velocity factor nor the dielectric environment just outside the radiating elements is super-critical. It IS important to get the element lengths right so the phasing of the feedpoints is right.

Once I understood, building one that worked right became pretty easy. Three steps: (1) use the coax VF and length to get the phasing right. Accept whatever feedpoint impedance that gives you. (2) Use a matching network (lumped or distributed, your choice) to match to that impedance. (3) Decouple the antenna from its surroundings (including but not limited to the feedline), so it can do its work properly. And I suppose (4) mount it up high and in the clear for best coverage. The rest is things like proper choices for good mechanical strength and reliability.

Cheers,
Tom

> EZNEC because (etc).

After the comments of Richard Clark and you, Roy, I attempted to use EZNEC to determine the ground wave (see link below).

The near-field analysis of EZNEC for radiation in the horizontal plane at a point 1 km from a 1/4-wave monopole having two ohms in series with a Mininec r-f ground, while radiating 1 kW over an earth conductivity of 8 mS/m is shown as 72 mV/m.

The same setup when analyzed using the FCC's radiation efficiency for this monopole height, and their propagation charts for these conditions shows about 295 mV/m as the result, which value is supported by the measured performance of real-world AM broadcast stations, and is also a value in a range that could be expected from the BL&E data.

Hopefully you or Richard Clark can tell me the reason(s) for this difference, which could easily be my own setup of the NEC model.

Roy, would you mind posting the ground wave value EZNEC Pro reports for these conditions?

>Excellent post.

Thanks. I'll add one more notch on my LCD frame.

>The problem with QEX is not enough submissions.

Well, they rejected one of mine many years ago. The problem was they never really said why. When I pressed the editor, he replied that he had enough submissions of sufficient quality. I tried again later and had it rejected because I wasn't an ARRL member at the time (because I was broke). I don't know what was going on, but I wasn't thrilled and never bothered again.

>As for the
>QST AM mods, I was thinking that was ATV, but maybe you were talking about
>something else.

Something else was converting commercial land mobile FM radios from WBFM or later NBFM to AM (A3A) modulation. Mostly, it was adding a low level modulation circuit, and converting the power stages from Class C to Class A or AB. To me, it was a little like publishing an article today on converting a Prius Hybrid automobile to only run on gasoline.

>The same applies to QST. If there aren't enough
>submissions, the only recourse is to hire writers to do columns or fill the
>empiness with drivel and ads like 73.

Probably true. I submitted an article in about 2002 on using the audio time delay through a repeater to do hyperbolic (Loran A style) vehicle location. I forgot why it was rejected because I ended up in the hospital and my memory from that period is rather muddled. When I inquired about the submission a year later, they said that they couldn't find it or that it was lost. Then, I mentioned that I still wasn't an ARRL member and all communications ceased.

>The best things to come out of 73 was
>the Star Trek communicator clone and Byte magazine. I hate how Ham Radio
>magazine died out.

73 published Joe Moell's column on amateur radio direction finding. To me, it was worth the price of a subscription. Before I tossed my archives, I ripped out and saved most of these issues. Wanna build a rotating antenna direction finder? The only references in ham radio land you'll find are in these 73 magazine issues. Same with various

microwave columns. I could have done without Wayne Green's endless
editorials.

>I was President of the local ham club for a while, and
>wound up doing the newletter too. For the three or four years of that, I

>pull out of my A** every month or go around like a reporter and interrogate
>people.

Our current newsletter editor complains about the same thing.
<http://www.k6bj.org>
Still, he manages to produce a superior ham radio newsletter. I used
to submit irregular technical articles and obnoxious opinionated radio
politix articles. However, one article that I spend considerable time
writing was butchered beyond recognition. When I asked for an
explanation, I got nothing. So, no more articles from me.

>On the other hand - What neat inventions can we come up with to share with
>the World, so it can be exploited and give reason to take more of our
>spectrum?

It probably shouldn't be an invention. More likely, an unusual or
interesting application of some existing technology. Your ATV camera
for disaster services is a good example. Direction finding is still a
common problem (i.e. stuck public safety transmitters). Perhaps
demonstrating how some of the dumb|great ideas originating out FCC can
be made to work (i.e. white space, ultra narrow band FM, on the fly
TDMA, etc). I could think of lots of useful things to build, design,
buy, or analyze.

>Interesting to note how public safety volunteers showed Los
>Angeles Sheriff how neat ATV was and they turned around and petitioned the
>FCC for those frequencies.

We had some floods a few years ago. The levee broke along the Pajaro
river. One of our members has a helicopter and volunteered to fly an
ATV camera over the area for the sheriff. On screen was GPS position
in APRS format. Everything worked and everyone was suitably
impressed. Then, nothing. No clue exactly why, but my guess is that
homebrew is not funded by Homeland Security.

>Oh well, we will probably all be shot in head by the next regime because we
>are an irritation.

Nope. We will all be promoted to a position of responsibility, where
we will be setup to fail, thus demonstrating that technologists are no
better at running the country than politicians, crooks, bureaucrats,
and thugs.

Nope. Art started it. You might want to enable threading on your
newsreader so it's easier to assign the blame.

While not guilty of the original sin, I am guilty of the lesser crime
of engaging in topic drift. I attempted to answer Art's accusations
against the ARRL and the universities. You then mentioned free
antenna articles hidden in secret university archives, and I expanded
on this distraction. It was of interest to me because it might
eliminate the necessity of shelling out $200 to the IEEE for
convenient access.

You also suggested that I might be a usenet troll. I've been accussed
of many things, but not of trolling. If I wanted to play troll, it
would be obvious and fairly evident.

So, back to my original diversion and topic drift:
1. Where this horde of university antenna design articles?
2. Do you think I should keep looking for this horde, or should I
give up now and shell out the $200.
3. After reading some of my 19,000 assorted postings, do you still
think I'm a troll?

I modeled their structures as they built them explicitly (they had
many variations), at the frequency they used, took readings at the
distance they reported. For your 1 kilometer distance (not one they
used), I get 303 mV/m at 3 MHz for their 70 foot radiator over a field
of 113 x 135 foot radials with an average ground conductivity. When I
use their distance of a mile, I get 188 mV/m, all else identical.
Their paper reports by formula that I should see 194.5 mV/m.

It would appear that with the average of the two distances, my model
accords quite closely to BL&E. That average would suggest results are
within an unreasonable accuracy given my experience with making RF
power determinations at the bench. However, my model is repeatable,
the paper is chiseled into the granite of history and your original
complaint seems to be moot.

Then I posted my result of using the near-field analysis of EZNEC showing a value much LESS than the "modeler" value for those conditions when using the BL&E data and the FCC curves.

Following that is posted:

From: "Richard Clark" <kb7qhc@xxx.net>
Date: Wednesday, November 26, 2008 3:32 PM

>I modeled their structures as they built them explicitly (they had

>Their paper reports by formula that I should see 194.5 mV/m. ...

No, the BL&E paper (accurately) stated that 194.5 mV/m is the theoretical maximum field possible at 1 mile for 1 kW radiated by a perfect 1/4-wave monopole over a perfect ground plane. The peak values they measured came very close, but never quite achieved that value.

>It would appear that with the average of the two distances, my model
>accords quite closely to BL&E.

Mr. Clark - kindly note that in your first quote above you say that, if anything, "modelers" show MORE response than BL&E Then when pressed a bit you say that your model "accords quite closely" with BL&E.

Yet the results of my EZNEC near-field model showed considerably LESS ground wave field at 1 km than either the FCC approach or the BL&E data.

Clarifications, please?

That's a quintessentially American point of view. I highly recommend _Anti-Intellectualism in American Life_ by Richard Hostadter. It helps explain why ignorance is such an asset to American politicians (and schoolchildren, for that matter), while intellectual accomplishments and ability generally have to be hidden. It won a Pulitzer prize, which of course proves that the author can't possibly have any common sense.

Can you explain why they very nearly accomplished this perfect ground value even though the ground wave signal had to propagate one mile over ground of finite conductivity? What do you think would have happened to the signal strength if the mile of intervening ground had been replaced by a perfect ground?

If you can answer the questions I asked above, you should understand why EZNEC doesn't predict the same value as the obviously (to me) normalized BL&E values. I'll look into the correspondence between EZNEC and FCC predictions.

The database will be on the internet. How the device will connect to
the internet is not stated in the ruling, but if the device cannot
transmit until it has consulted the database it won't be by talking to
another TVBD.

No? No what? Is your rejection rhetorical? a dramatic conceit? Is
there some cognitive gap between "by formula" and "theoretical" you
are trying to mine? To what purpose?

Are you demanding an exact accounting between measured vs. modeled? If
so, my model comes within 2mV/m of their graphed data (which, in its
own right, does not mean they actually measured that particular
cardinal point but as it encompasses their explicitly stated variables
is tantalizingly close enough). Expectations of accuracy performed in
the field for a continuum of points (verging on 1%) for a fabricated
argument of more/less is seeking advantage where there is no salvation
to be found.

>>It would appear that with the average of the two distances, my model
>>accords quite closely to BL&E.
>
>Mr. Clark - kindly note that in your first quote above you say that,
>if anything, "modelers" show MORE response than BL&E Then when
>pressed a bit you say that your model "accords quite closely" with
>BL&E.

There is more than one model involved as described by BL&E. I
explicitly selected from one of several available - all of which I
have modeled. The model I describe conforms to far more of their
variables available than those expressed by you. It also exhibited
more response than your 1kM touchstone. Is this touchstone derived
from BL&E or some other source unknown to all here, but you? It seems
when I followed your offering, you want to challenge its authority.

Those two data points I offer exhibit variations of barely a quarter
dB about the touchstones you supply (one available from BL&E), and
which you fall considerably short of in your own effort. Their
average around these touchstones average is an amazingly small

difference. The difference between the model I selected, and the one they report (one in the same) is on order of 0.1dB. If this does not constitute an accord, then I would suggest you have more water to carry than myself to turn modeling results into congruency. I am not particularly motivated to improve things when my experience suggests that it is a fool's mission given it implies accuracies that were beyond what was achievable in that cold winter field, 70 odd years ago.

>Yet the results of my EZNEC near-field model showed considerably LESS
>ground wave field at 1 km than either the FCC approach or the BL&E
>data.
>
>Clarifications, please?

You don't provide enough detail of your model to be able to point to anything in error, but by the multitude of your statements, it doesn't sound like you have spent enough time in the practice of modeling. The rest of my discussion below hardly reveals anything beyond the obvious - for one versed in the craft.

My models were arrived at through the simple, but tedious craft of close reading and conforming to expressed facts in the literature. Some art was involved in the selection from a choice of grounds, for which such choice drives a wide variation of results. Does this sound familiar? Even there, calling it art denies the information supplied by photographs revealing a very commonplace description: Pastoral. My choice of ground characteristics, if anything, hardly exhibits a radical departure. In fact I choose no other ground than average for the vast majority of my modeling. Within the confines of the abilities of the model to support buried wire, that was performed by suggestions offered in the help manual (clarity is achieved in reading that too and is generally obtained in the course of considerable exposure to the toolset). Here, the radials hovered less than half an inch above ground instead of buried six inches beneath. Perhaps this explains the remaining 0.1dB variation, but I doubt it. To infer such tight coupling between model and measure is a fantasy only Art would embrace to prove we can't trust established theory.

As a matter of fact skin depth tends to keep power conductors (50/60
Hz) below 1 inch (25 mm) diameter. It becomes easier and cheaper to
"quad them up" (four conductors a couple of hand spans apart).

There is a correction that should be made here. Polyvinyl chloride has high radio frequency losses, and the addition of plasticizers usually increases these losses. But these dielectric losses are NOT due to conduction. Rather, they are the result of hindered rotational movement in the chemical dipoles within the polymer structure itself. In an insulator, when an AC voltage is applied, most of the current through the capacitor formed by the insulator leads the applied voltage. In a perfect capacitor, the current leads the voltage by 90 degrees. But in a real capacitor, the insulator has dielectric losses which means that the current leads the applied voltage by less than 90 degrees; i.e. a portion of the current is now in phase with the applied voltage. This current produces heating of the insulator. AT A GIVEN FREQUENCY, the capacitor acts as if is a pure capacitance in series with a resistance (or in parallel with a conductance). This model of a real capacitor is only valid at that ONE frequency. At DC, for example, most capacitors show extremely little conduction. Their insulation resistance can be over 10^10 ohm-cm. At high RF frequencies, the dielectric loss increases.

In the case of polyvinyl chloride, which is a hard, very brittle material, additives known as plasticizers are compounded into the PVC to produce the desired mechanical properties. A little plasticizer makes PVC tougher and easier to process. A lot of plasticizer makes PVC soft and pliable. Clear vinyl tubing can be as much as 40% plasticizer. Plasticizers are not chemically attached to the PVC polymer. This means that over time, the plasticizer can leach out or evaporate from the soft vinyl, leaving it hard and brittle again. Everyone is probably familiar with vinyl automobile seat covers. When your car is parked in the hot sun, a portion of the plasticizer evaporates out. Eventually the vinyl cracks and tears, and you wind up with a greasy, difficult to remove, oily film on the inside glass of the car. The plasticizer has left the vinyl, causing the cracking, and

condensed on the glass making a greasy mess. The sticky, gooey mess seen on old vinyl power cords is also due to the plasticizer leaving the PVC and accumulating on the surface.

Did you ever wonder what was meant when coaxial cable was described as having a non-contaminating vinyl jacket? This means that the plasticizer in the cable jacket leaches out, but very slowly compared to the service life of the cable. In older, and cheaper coax cable, conventional plasticizers are used which leach out or evaporate fairly quickly. This makes the cable stiffer and more prone to cracking. But long before this happens, the plasticizer has migrated into the polyethylene insulation surrounding the inner conductor, greatly increasing its RF losses. This can take just a few years. In some of the newer cables, a foil or metalized polyester layer surrounds the polyethylene under the shield. This effectively prevents the migration of the plasticizer.

To go back to the antenna issue, polyurethane foams of low density (lots of void space) have a low dielectric constant and small loss tangent (small dissipation factor). "The Handbook of Antenna Design" By A. W. Rudge, K. Milne, A. David Oliver, and P. Knight, has a discussion of high strength polyurethane foams as radome materials. However these foams are different from the "Great Stuff" foams in a can that you buy at the local hardware store. These foams are moisture cured so their dielectric losses will be somewhat higher. Do not confuse these with latex foams which have much greater dielectric losses. Also remember that these uncured urethane foams have 4,4-methylene bisphenyl isocyanate as one component. This is a nasty material from a safety viewpoint (a skin and lung allergic sensitizer), so follow the instructions carefully about gloves and eye protection.

To conclude, I would avoid the PVC material as a protective cover. Most common fiberglass tubes are either fiberglass/polyester or fiberglass/epoxy composites. Both materials have some dielectric loss but far less than PVC. Urethane foam will be a fairly good material to hold the antenna rigid within the tube. However the tube and the foam WILL detune the antenna meaning you will need to do some experimentation before you can produce the desired results.

Conditional access has been done with analog -- but not well. I sucessfully
defeated analog scrambling with two different home-brew devices but I never
tried digital. Too hard.

It's much easier to hard-code C/A with digital.

Just my two cents.

Good. I don't mind spending the time if you're willing to build it.
None of my objections are particularly fatal. However, I would
suggest you at least investigate alternatives, which in my opinion,
work better (and are easier to build). For example, the 4 bay stacked
vertical folded dipoles, with coaxial power dividers, is far less
complexicated, and methinks works better. I was building these for
463/468MHz in about 1968(?) out of strips of 1/2" wide aluminum and
pop rivets. If you're interested, I'll see if I can find some photos
or scribblings. There are a few in this photo:
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn02.html>
but I can't distinguish mine from the stock dB Products antennas.
Incidentally, that's a great example of how *NOT* to install antennas.
Those are all transmit antennas with no ferrite isolators. The
intermod generated was monumental.

Some more examples of commercial versions:
<http://www.radiowrench.com/sonic/so02202.html>
<http://www.radiowrench.com/sonic/> (look for dB Products PDF's)

>target frequency is around lets say 418MHz (that's not really it, I like to
>remain anonymous).

Y'er no fun.

>It was interesting what you said about the radome and how
>it detuned the antenna. Do you think it was mainly the PVC or the urethane
>foam that caused the issue.

Both. I suspect you have a sweeper and some means of measuing
reflection coefficient or VSWR in real time (on a scope). If not, the
reflection coefficient bridge is easy to build. Take any antenna you
look at the VSWR curve on the scope. Then, shove the pipe over the
antenna and watch what happens. If the tubing were fiberglass, some
thin plastics, or glass, nothing will change on the scope. PVC and
ABC will detune the antenna. So will common fence post compound
(urathane foam) but to a lesser degree. Packing the empty space with
styrofoam or styroam peanuts seems to work well enough and result in a
repairable antenna. Real fiberglass tubing (masts or marine hardware)
is easy enough to obtain, that I wouldn't bother with PVC. Besides,
fiberglass is nice and stiff, while PVC flops around in the wind.

>I plan to use a fibreglass tubing and spacers so
>hopefully I don't see as much near field effects as you did.

Yep. There's always hope.

>I have learned
>that some PVC pipes have certain conductive additives and are not so good
>for antenna use, plus it might be tough trying to sell a 'poop pipe' antenna
>commercially if it ever became a product of ours.

If you want to try a real disaster, try black drainage PVC pipe.
Carbon filled. For a good acid test, try putting a pipe section in a
microwave oven. If it stays cold, you win. If it gets hot, thing
again. If it melts and catches fire, forget it. It's also fun to
take an ordinary 440 yackie talkie or scanner, shove a piece of PVC
pipe over the antenna, and listen to the signal change. I like to do
this demo at radio club meetings. The best of the bunch is
fiberglass. A close 2nd is white ABS (acrylo-nitrile butadene
styrene) which is a bit difficult to find. It's commonly used in
vacuum forming and commonly found on GPS antennas and such.

>Do you happen to know if I should be using a odd or even number of half wave
>elements in my design? I'm beginning to think it doesn't really matter.

It matters quite a bit. However, I can't offer an answer. Some
designes use the bottom section as a matching transformer or
counterpoise. That mangles the count. I would have to see what
you're doing to make the determination.

Also, I could probably figure it out, but it's midnight and I'm beat.
I spent 5 days last week fighting a kidney stone and am still kinda
wiped from that. If you can't figure it it, bug me and I'll do the
dirty work. A good clue is that the center conductor of the input
coax connector must connect to the center wire which goes to the 1/4
vertical whip section at the top.

Also, there are patents worth reading:
<http://www.google.com/patents?id=JMweAAAAEBAJ&dq=6947006>
<http://www.google.com/patents?id=qDYWAAAAEBAJ&dq=6947006>
<http://www.google.com/patents?id=XpgfAAAAEBAJ&dq=6947006>
etc. The accompanying explanations are usually sufficient to figure
out how it works. You might notice that one of the construction
methods is applicable to your copper tubing idea.

> Can you explain why they very nearly accomplished this perfect ground
> value even though the ground wave signal had to propagate one mile over
> ground of finite conductivity?

BL&E made their surface-wave measurements 3/10 of a mile from their 3 MHz monopole transmit site.

MW ground loss for the surface wave across a path that short is low, regardless of ground conductivity. This may be seen in the scan linked below, which was taken from Terman's Radio Engineers Handbook, 1st Edition, page 681.

The scan doesn't show distances less than 1 mile, and the curves are based on higher ground conductivity than BL&E had to work with -- but an extrapolation of those curves to the BL&E conditions should convince most reasonable readers of the conclusion in my paragraph above.

The BL&E paper published in the Proceedings of the IRE states (page 771) "For each antenna height, 0.2 watt of power was fed into this antenna, and the field intensity was measured at 0.3 of a mile. This figure was then converted to a basis of a power of 1000 watts and a distance of one mile."

So BL&E did not normalize their readings to account for ground loss either at 3/10ths of a mile or one mile, but apparently they did assume that the effect of the ground loss was the same at those two distances. That error would not be large, however.

>What do you think would have happened to the signal strength
>if the mile of intervening ground had been replaced by a perfect
>ground?

They would have measured 194.5 mV/m, referenced to 1 kW of radiated power. As it was, they reported about 191 mV/m (max).

If you are happy with the results of your modeling, then well and good
for you.

But the near-field value calculated by EZNEC and as shown in my URL is
far short of the result of the BL&E study, and also of the FCC's
propagation curve value for those conditions.

So far neither you nor Roy has suggested that the near-field analysis
I posted was based on an incorrect model, and there was enough
information about it in my clip to determine that.

BTW, a distance of 1 km from a 1 MHz, 1/4-wave monopole is no longer
in its near field, the boundary of which in this case is less than 150
feet from the monopole.

No, KGB don't HAVE to manipulate idiots. They manipulate the intellectuals, who in turn lead the idiots until they all wind up in a ditch. They only serve purpose to destabilize and demoralize. There is no place for them in normalization phase because they find they have been duped and become bitter enemies. It is better they be liquidated first in the normalization phase.

Ah, we are working from a script. I am suggesting that your model is
incorrect. You asked what to do, I would suggest fixing it. You have
been provided with the necessary references. Let us know when you
succeed, but skip reports of failure. As you say, you have already
provided enough information.

I'm anxious to get started so I've put my copper pipe design on hold well I wait for parts and decided to start with a coax approach. So I hit the hardware store and got some PVC pipe and mounting bits. I understand that the PVC is not as good as fiberglass because of it's near field effects, BTW if you can tune those effects out, what is the end result in loss? I plan on using LMR-200 because of it's slight rigidity and it's high velocity factor (83%). I bought 1-1/2 inch rubber washers with a 3/16 hole in the center that will slide over the coax and then be pulled into the 1-1/4 inch PVC this will center and support the coax up the length of the pipe. I will try using some clamp-on ferrites that we have laying around to stub the currents on the feed line and slide them around and see if I can tune the antenna using the network analyzer. I still don't understand what that quarter wave whip is suppose to do that sits on top of the array and I think I will try to omit that in my first design (unless someone convinces me otherwise).

Anyways, time to get my hands dirty and build me an antenna!

Thanks Barry for the in-depth enlightenment of radome material :) Do you happen to know the answer to this question: When you tune the near field effects of PVC out, what is the end result in loss? and how is this compared to fiberglass?

Yep, for Clients, I use 12dbi Panel Antennas, which are very compact and
provide the required F/B Ratio and gain, for each link.

Jim
IEEE state that if papers were open source it would threaten the
presence of the IEEE?
This statement was in regard to the high costs of obtaining copies
from the IEEE without
having to pay the high costs of belonging . I understand the need for
peer review by academics but not necessarily a private entity
and the IEEE rights to publish such so, are the IEEE demanding SOLE
ownership of presented papers?
I am assuming that all papers presented by the Universities as well as
thesis papers belong to the parent university
based on a recent antenna patent awarded to a University derived from
a student dissertation. This leaves
an outstanding question !. If the university a public entity,
reserves the rights of all papers arrived at the university
then what rights do they hold that allows transference from the public
domain of those rights to a private institution to the detriment of
the public
that finance them?

You gave no characteristics of the NEC construction and settings for your model (cogent or otherwise), as I did for mine. You only stated the results you say you got.

Even Roy Lewallen wrote that he will look into the correspondence of my EZNEC solution with the FCC value for those conditions -- which Roy probably wouldn't choose to do if there was good agreement between them, or my "near field" model was obviously incorrect to him.

Schedule 40, schedule 80, water, or electrical? They're all
different. Did you at least do the microwave oven test on a small
piece to see if you're headed for a problem? I've had a few surprises
with different vendors and styles.

>I understand that
>the PVC is not as good as fiberglass because of it's near field effects, BTW
>if you can tune those effects out, what is the end result in loss?

No. You can't make the radome (pipe) big enough to get out of the
near field. Minimum is a few wavelengths.

Try a chunk of PVC over your 440 HT or scanner whip antenna and see if
you want to continue blundering along this path.

>I plan
>on using LMR-200 because of it's slight rigidity and it's high velocity
>factor (83%).

The added rigidity doesn't buy you much if you're going to shove it
down a pipe.

>I bought 1-1/2 inch rubber washers with a 3/16 hole in the
>center that will slide over the coax and then be pulled into the 1-1/4 inch
>PVC this will center and support the coax up the length of the pipe.

Why such a large diameter pipe? There's no difference in loss.

>I will
>try using some clamp-on ferrites that we have laying around to stub the
>currents on the feed line and slide them around and see if I can tune the
>antenna using the network analyzer.

Got a ferrite that works at 418MHz? Even if the ferrite does work,
the RF its blocking is converted to heat. Wouldn't it be better if
you built a proper matching contrivance to that RF is radiated instead
of absorbed? I suggest you lose the ferrites and band-aids as they

tend to hide design errors and inefficiencies.

>I still don't understand what that
>quarter wave whip is suppose to do that sits on top of the array

I hate easy questions. If you look at the construction of the alternating coax sections, the top section will be one with the hot RF lead eventually connected to the outside of the top coax section. In other words, the outside of the coax is the radiating element.
<http://www.rason.org/Projects/collant/collant.htm>
Why bother using another coax section when it would be easier to just use a piece of wire? Look at the Fig 3 drawing and just follow the RF path from the coax entry at the left to the 1/4 wave element on the right. That might also answer your question about odd/even sections.

>and I think
>I will try to omit that in my first design (unless someone convinces me
>otherwise).

Not recommended, but you have the test equipment to determine if it's a good or bad idea. Ummm... you were planning on testing this thing?

>Anyways, time to get my hands dirty and build me an antenna!

Good luck, but first a little math. What manner of tolerance do you thing you need to cut your coax pieces? Let's pretend you wanted to get the center frequency accurate to 1Mhz. At 418MHz, one wavelength is:
wavelength(mm) = 300,000 / freq(mhz) * VF
wavelength = 3*10^5 / 418 * 0.83 = 596 mm
That works out to:
596 / 418 = 1.4 mm/MHz
So, if you want the center frequency accurate to within +/- 1MHz, you gotta cut it to within +/- 1.4 mm. Good luck. Like I previously ranted, you'll need a cutting fixture. A steady hand, good eye, quality coax, and plenty of patience are also helpful.

Incidentally, since the top 1/4 wave element represents something close to perhaps 50 ohms, it would be interesting to measure the amount of RF that isn't radiated and actually gets to the top section of the antenna. If my analysis of the antenna is correct, the first section (near the coax connector) radiates 1/2 the power. The next section 1/4th. After that 1/8th, etc. By the time it gets to the top of the antenna, there won't be much left. However, that's theory, which often fails to resemble reality. It would interesting if you stuck a coax connector on the top, and measured what comes out.

Happy Day of the Turkeys.

> compared to fiberglass?

When you tune the antenna to compensate for its surroundings, usually by shortening the elements since the real portion of the permittivity of the close surroundings is capacitive, you just have to accept the added loss due to the imaginary portion of the permittivity, the dielectric dissipation.

When designing a radome, look for a material with the lowest dissipation factor (or loss tangent which is another way of describing the dissipation losses). The added capacitive reactance can be tuned out, but it is still best to use a material with a low dielectric constant. This does not say that the antenna pattern will not be affected, however, as the antenna lengths and spacings are changed.

A good analogy to illustrate this is the fact that an aircraft cannot be perfectly stealthy. If the aircraft is made entirely from microwave transparent material, the difference between that material's dielectric constant and that of the surrounding air will still generate reflections that will show up on radar. In fact, if you make the aircraft out of completely absorbing material, the bow wave compression of the air will create a slight dielectric discontinuity which still reflects microwaves. Of course, the radar cross section will be far smaller. The idea is to make the radar target appear so small that it is ignored.

While the dielectric constant of PVC is slightly lower than fiberglass reinforced polyester or fiberglass reinforced epoxy, its lost tangent is higher. Also, the mechanical strength of PVC is less than the fiberglass reinforced plastics, so you can make the radome thinner with the FRP materials. This benefits the detuning as well as the losses.

Before closing, I would like to comment on an additional related issue brought up by my friend AE6KS...

"Jeff Liebermann" <jeffl@cruzio.com> wrote in message

>
> If you want to try a real disaster, try black drainage PVC pipe.
> Carbon filled. For a good acid test, try putting a pipe section in a
> microwave oven.

I would be willing to bet that the carbon black had little to do with the losses. It only takes a tiny amount of carbon black to make the plastic quite black looking and to provide good ultraviolet light protection - just a few percent at most. I once needed a good microwave absorber for an instrument I was building. Not wanting to wait on Emerson & Cuming to sell me some of their ECCOSORB &#65533; material, I decided to make my own. Just down the hall was our polymer testing lab where they could blend polymer chips with various additives and mold me some 4" x 4" blocks from the blend. I decided to have them make a polyethylene blend with 30% carbon black added. The finished material was a dull black, and it would even leave nice black marks when rubbed across paper. I was confident when I placed a 1/2" thick block of the material between two WR-90 10 GHz flanges that it would not let much signal through. Boy was I surprised when it offered very little attenuation! It took a while to think about what was happening. The polyethylene was a low loss dielectric material at these frequencies, and the carbon black particles were extremely small. The result was a plastic that contained conductive particles that were insulated from each other. The particles were so small that even at 10 GHz, they were far too small to couple much microwave energy into them. What I really needed was long carbon fibers that made electrical contact with each other in the plastic. I didn't have time to study this as the Eccosorb arrived and I used it in my instrument. But it taught me a valuable lesson about absorbers.

By the way, http://www.eccosorb.com has a number of good technical tutorials on absorbers and dielectrics.

I was once spending $140 a month for digital cable and net service. I
dropped all the cable tv services, bumped the net service up to the 25/7
service and now watch via hulu.com, surfthechannel.com, youtube, and
network TV sites.

Cable television is pretty much dead now.

When I observe the operational characteristics of EZNEC (you report
you use it above) AND I observe that it does not offer a Near Field
analysis for Mininec r-f ground (as you report you use above) THEN I
have to wonder how you arrive at a figure of 72 mV/m (as you report
you obtained above). Other than version differences or updates in the
program that supercede mine, I rely on the advice found in the Help
manual provided:
>>Near field analysis is disabled when MININEC-type ground is selected.
>>...Use some other ground type for near field analysis.

Your failure to heed this advice seems consistent with your repeated
ignorance of EZNEC's capacity to perform Near Field Analysis. Also
consistent is the complete absence of radials in your model - the
hallmark (cogent) research of BL&E's "Ground Systems as a Factor in
Antenna Efficiency." This consistency propagates into your near field
report - where did you get
>>>is shown as 72 mV/m.
from?

Did you achieve this valuation through a novel upgrade feature found
in EZNEC 5? If so, I bet the help entry still suggests that mininec
type ground is not preferred (and that you ignored that commentary
too). The differences in models to replicate BL&E results well
illustrates this for any version issue you may reveal.

Greets OMs,

yesterday i had a QSO with K2US - impressive antenna, by the way i'm using the station of a local OM near my QTH with a 4 elements 5 band Quad.

The beautiful thing is the 9-9+20 signal around 20.45 UTC, far away in magnitude from the others stateside signals, around S5-7. So i remember my father that tell me one day in his opinion the circular polarization in the better choice... lose no matter about 6 dB, with any kind of polarization used at the other side except circular - and faraday torsion due to ionosphere - and in my mind comes 2 questions...

- we take some advantage from the fact that both are using quad antenna ??
- in my non-knowledge of the facts, i have in the past believed that the quad antenna is near a circular-polarized antenna. Reading books and hearing some QSO in the air i learn that quad can be horizontal or vertical polarized, regard the feed point of the quad.. so - the circular polarization need some kind of "special" feed point or is merely a "circle" antenna ??

Apologize for the english and for the questions, maybe trivials and stupids, but i believe one esxperienced OM can say far better than 100 books.

Obviously, near-field analysis was not disabled by/in EZNEC for my model definition. The surface-wave value of 72 mV/m at 1 km for 1 kW of radiated power is shown in the screen clip I linked to in my first post about this.

>Also consistent is the complete absence of radials in your model - the
> hallmark (cogent) research of BL&E's "Ground Systems as a Factor in
> Antenna Efficiency."

The r-f loss of the radial system is accounted for in my model by the two ohms of resistance inserted between the base of the monopole and ground, as shown in my screen clip. This two ohms is approximately the r-f loss of a set of 120 buried radials, each 1/4-wave in physical length.

The peak gain of the elevation pattern in my model (see my screen clip) is consistent with such a ground loss and the selected ground conductivity, so this approach appears to be valid.

Hopefully Roy Lewallen will weigh in, as he has time, to comment on the methods and results of our two analyses -- although probably Roy will need more details about your model construction than you have so far been willing to provide.

I will be content to let the chips fall where they may.

Circular polarization means you have equal H-Pol and V-Pol radiation,
with one polarization 90 degrees ahead (or behind) of the other.

A quad antenna is a folded dipole.

a quad is generally linearly polarized, either vertical or horizontal. to
get circular polarization you need dual driven elements with the proper
phasing.

Except the top and bottom arms of a horizontally polarized quad element
are far enough apart to provide some gain and to slightly lower the
pattern from that of a dipole at the quad's central height. In a four or
five element design this can be quite effective. I was on the far end of
the QSO (at VE8ML) back in 1965 when OH8OS tested some very large quads

on 15m. They were impressive.

Ya but they're putting commercials on the web episodes too! You cant get away from whatever they want to jam into the stream!

I still have my VCR. I don't mind FFwd every few minutes. After all, if you have seen the commercial once, you have been "informed". I caught a couple of episodes of Sarah Connor Chronicles on the web and quality was pretty good but they played the same ad over and over until I found myself singing to it, so that I had to smack myself in the head with the phonebook to reboot myself.

Hi MG

It isnt at all so simple as feeding one radiator 90 degrees later than another to get "circular" polarization. For instance two linear radiators can be fed in phase to get "CP". And two linear radiators can be fed with one 90 defrees earlier (or later) than the other.
Look at wikipedia http://en.wikipedia.org/wiki/Circular_polarization

I'd expect that you can feed two Quads in phase to get CP along the axis of their mounting boom. You'd space them appropriately and conect their fed points appropriately.

Your first problem, which seems to negate your entire statement(s), is
the obvious error in your definition of "intellectual." Anyone make
those error in reasoning/thinking is far from an "intellectual",
although very young ones might make those errors.

An exact example of what the error(s) you are making was given with John
Mccain--the IDIOT "intellectuals" called him a war hero!

Now, someone who was ONLY able to become a pilot because his father was
an admiral and exerted his influence, smashed up five planes
(http://www.vietnamveteransagainstjohnmccain.com/cin_mccain_lost_five_u.htm)
and was captured by the enemy and held for five years is NOT a true "war
hero" in the true meaning to the term ...

... idiots abound, you can know them by the errors in the reasoning,
text and thinking ... idiots can't ... :-(

where the question remains at:
>> where did you get
>>>>>is shown as 72 mV/m.
>>from?
It is evident your field quote is NOT from this specific Mininec r-f
ground model of yours above.

As you admit you had near-field analysis available above (you still do
not explain how in the context of a mini-nec ground per your stated
model's characteristics), and you do not describe any radial treatment
(cogent elements of the BL&E paper "Ground Systems as a Factor in
Antenna Efficiency"), and you do describe a 1/4 radiator (not found in
BL&E experimental data), then your call for suggestions on how to fix
your model's failure in the context of BL&E becomes an obscure moving
target. My "suggestion" alters slightly with do it right or discard
it as trash. There aren't really many other alternatives.

>Hopefully Roy Lewallen will weigh in, as he has time, to comment on
>the methods and results of our two analyses -- although probably Roy
>will need more details about your model construction than you have so
>far been willing to provide.

More interesting would be his enquiry or explanation into how you
defeated the lock-out for a feature that is a poor method for near
field analysis. I find it more intriguing in how you embrace it in
spite of stated cautions to employ other methods. Yes, this novel
adaptation of Mininec r-f ground to near field solutions bears more
explanation from some source. I cannot imagine that explanation will
improve your model's performance to equal mine however. That is
already well evident.

As for more details, the BL&E paper "Ground Systems as a Factor in Antenna Efficiency" is the totality of my sources. Those practiced in the craft of modeling and proficient with its tools will find it sufficiently informing if they hadn't already proceeded to a successful implementation from my descriptions in this thread.

Yes, there is much I have experienced there ...

We have dishtv, you can record shows/movies to the DVRs' recorder and
then click a few times to go through 3-5-7-or more minutes of
commercials ...

Still, just the "feel" and the "stress" of all this leaves me with a bad
taste in my mouth; when I mentioned that to the wife, she carried on
for a good fifteen minutes+ on her own "emotional distress."

This is just all about what a person is able to accept, or not, some
might not even notice any "discomfort."

AT&T is the first "BIG one we took on", we dropped them and went to
Vonage--that was unacceptable at $29.?? a month, for the service we
received--in short, and my humble opinion, they are a ripoff. We now
use magicjack (http://www.magicjack.com) as $20 bucks for the little USB
dongle, then $20 bucks a year, thereafter, to call all the US and Canada
for free--we found our phone service!

Can you not view the screen clip at the link I posted showing this?
Why do you keep asking?

All of the windows shown in my screen clip resulted from the NEC model data appearing in the upper left window of that clip, and all windows in the clip appeared on the screen at same time and were driven by that data. Note the selection of a Real/MININEC ground in the EZNEC window in the upper left corner, and the further selection of a "medium ground" on the line below. One of the other windows there shows the "near-field" value of 72 mV/m at 1 km for 1 kW of radiated power for this model. Are you comprehending all that is shown in that clip?

> More interesting would be his enquiry or explanation into how you
> defeated the lock-out for a feature that is a poor method for near
> field analysis.

No defeat of such was necessary. EZNEC produced the data results for my model exactly as shown in my screen clip, with no complaints or subterfuge on my part.

>Can you not view the screen clip at the link I posted showing this?
>Why do you keep asking?

Because in a commercial release, suitable to professional and
scholarly reporting, it is obviously locked out as an available option
- by design and documented as so. A screen shot does not describe
your actions. You need only explicitly state that when you selected
the mini-nec ground model, that you had the NF button available and
you selected it. If such is the case, it is a bug in Roy's demo -
caveat emptor. I don't do research with demo applications.

The long and short of it is that what your poor model reveals is a
departure from the data found in the BL&E paper "Ground Systems as a
Factor in Antenna Efficiency." You
1. do not have a construction of radials of any type;
2. do not have a radiator sized to their specification;
3. employ an engine (mini-nec) which is poorly suited to the task;
4. excite the model at a frequency not supported in data in BL&E;
5. fail to note the documented advisories about near field operation
below 3MHz when such analysis is available.

There is no point in asking for how to "fix it" when your model is
irreconcilably crippled. Using a demo version of EZNEC is not suited
to the task. You couldn't even use my model as it is constructed with
fine granularity that exceeds the capacity of EZNEC, and supported
only with EZNEC+. There are alternatives that are free, and unlimited
in their segment counts available which is necessary for a proper
analysis. Caveat emptor still prevails, and you get the quality of
support you pay for.

I would "suggest" given all the cautions, contrarian advisories
offered, and warnings direct from the tool's author, that their
cumulative effect would seem to doom you to disappointment if you
demand something better than several percent concurrence to the data
supplied in the BL&E paper "Ground Systems as a Factor in Antenna

Efficiency" when abstracted to other applications.

Hello,

I made an excel sheet to simulate Fresnel diffraction patterns. I used a 2 way data table to generate the "infinitesimal" contributions from the EM field. After summation of the contributions in the 2D tables, a have one result cell (that holds |E|) and three input cells (variables) for x-, y-, and z- coordinate for the observation point. When I change the coordinates manually, the results seem OK.

The idea was to use another table (one way table) to plot |E| versus one of the input cells. However, I cannot get the table working. I tried "scenarios" (filling in each scenario by hand), but Excel stores the individual worksheets, so I ran out of the EXCEL 2000 internal memory limit (I think of about 60MB). I also tried the offset function, in combination with a one-way table. This also didn't work.

It seems that once you use a data table that uses one (or two) of your variables, you cannot use another table to manipulate a third variable (parameter).

Does somebody know a solution for this (I do not prefer a VB one)?

Best regards,

Wim

Hi Wim,

You might try OpenOffice Calc (part of the entire OpenOffice suite). I
have no direct experience in the matters you are having difficulty
with, however.

To humor you, then... I explicitly state that when I selected the Real/ MININEC ground model, I had the NF button available and that I selected it. The result of that analysis is included in the screen clip at the link I posted, and which you seem unable to comprehend.

Also please note that I have already described and documented my EZNEC model and actions in far more detail than you have done for yours, so far.

Note further that the Demo versions of EZNEC operate exactly the same as the paid versions, except for the number of segments permitted in the model -- which was not a factor in the model I constructed. I'm sure that Roy or someone else will correct me if that statement is provably wrong.

> The long and short of it is that what your poor model reveals is a
> departure from the data found in the BL&E paper "Ground Systems as a
> Factor in Antenna Efficiency." You

>1. do not have a construction of radials of any type;

Their effect was included as I described in an earlier post. I will understand if this concept evades you.

> 2. do not have a radiator sized to their specification;

A 1/4-wave monopole is a 1/4-wave monopole, regardless of the operating frequency. The intrinsic radiation envelope for a given radiated power actually launched by such a monopole (e.g., apart from the effects of the propagation environment) is the same at all those frequencies.

If not, the FCC would/could not have adopted the results of the BL&E experiments at 3 MHz as applicable to the entire MW AM broadcast band (which they did).

> 3. employ an engine (mini-nec) which is poorly suited to the task;

A MININEC ground itself is not an engine. It is a only a condition used by the NEC engine.

> 4. excite the model at a frequency not supported in data in BL&E;

See my response to your 2 above. In reality, surface-wave ground losses in the MW BC band are less than at the 3 MHz freq used in the BL&E studies, so the applicability of their findings is even more relevant to BC operations.

> 5. fail to note the documented advisories about near field operation
> below 3MHz when such analysis is available.

No such advisory was presented by/in EZNEC during the process of generating and analyzing my model.

I suggest you cool it for a while, and wait to see what Roy Lewallen might post about all of this.

But why would you care to try to get it within 1MHz? With only four
radiating elements, the beam 3dB width will be roughly 8 degrees if
the bottom of the antenna is a wavelength above ground (30 degrees in
freespace...). There's not much point in putting a lot of effort into
get closer than perhaps 4 electrical degrees along the line, and I
don't believe even that is necessary to get good performance. That's
several mm, and should be easy with such short lengths. Using foam-
Teflon coax makes it easy to do: the insulation doesn't melt when you
solder things together. I cut the sections to matched lengths, use a
little jig to trim the layers to the same lengths on each, and then
put a wrapping of 30AWG or so silver plated wire (wire-wrap wire)
around each joint to hold it while soldering. That makes it easy to
adjust before soldering, and solid after.

> stuck a coax connector on the top, and measured what comes out.

There's very little loss in a half wave of decent coax at 450MHz.
That means that the voltage across the lowest junction between
sections is echoed up the antenna at each other junction. In
freespace, by symmetry, the currents will be very nearly the same
going down from the top as going up from the bottom. My model over
typical ground (bottom a wavelength above the ground) shows current

symmetry within a percent or so, assuming equal voltages driving each of the three junctions. If you wish, you can use the parameters of the line you're actually using to figure the differences among the feedpoint voltages, based on the loads at each junction. When I've done that in the past, the differences are practically negligible. You can iterate, feeding those voltages back into the model to find new load impedances, etc., repeating till you're happy that the models have converged. Recent versions of EZNEC even let you put the transmission line into the model, along with its loss.

The supporting tube certainly will affect the feedpoint impedance, but in my experience, it does not materially affect the pattern. I deal with the impedance through a matching network; it's no trouble to adjust for a low enough reflection that I don't worry about it. Decoupling is the more interesting problem, to me.

Cheers,
Tom

Source record: 19668

It's possible to run a near field analysis using MININEC type ground with some v. 4.0 and all v. 3.0 and earlier versions of EZNEC. However, the results will be wrong. The problem with using near field analysis and MININEC type ground was discovered while v. 4.0.27 was current, and the restriction preventing that combination was introduced at v. 4.0.28 in August 2006. So only v. 4.0.28 and later programs have this restriction. Please see the last paragraph of this posting for remedies.

In EZNEC v. 4.0.28 and later, the NF Tab button is greyed out whenever a MININEC-type ground is specified. If it's clicked, you'll see a message that near field analysis is disabled when MININEC-type ground is specified. If you click Help in the message window, it'll open the manual topic which discusses real ground types. There, you'll find:

Near field analysis is disabled when MININEC-type ground is selected.

Tests have shown that, because of the fundamental way NEC does calculations, near field analysis with MININEC-type ground can produce significantly erroneous results, particularly in the vicinity of a wire which is connected to ground. This is really a contrived situation anyway, because the only way to achieve a ground connection for a real antenna comparable to the MININEC-type ground model is to install a radial system. This will alter the ground conductivity and local fields, so the MININEC-type ground model isn't really representative of conditions near a grounded wire in any case. Use some other ground type for near field analysis.

If the conclusion that EZNEC near field results differ from the FCC ground wave predictions is based on a near field analysis with MININEC-type ground, I'm not surprised at the disagreement. The analysis should be redone with a large number of radials just above the ground, and High Accuracy ground used instead of MININEC-type ground.

Two reminders:

1. As explained in the EZNEC manual, "near field" analysis isn't restricted to the near field. It's actually "total field" -- including ground wave -- and is accurate at any reasonable distance. The "near field" nomenclature is carried over from NEC.
2. The EZNEC ground model is flat and infinite in extent. So the predicted direct line field begins deviating from actual field values where the curvature of the Earth becomes a significant factor.

Anyone using EZNEC v. 3.0 and earlier should avoid using the combination of near field analysis and MININEC-type ground. Anyone using v. 4.0 should update his program to the last revision of that version, 4.0.39. You can find instructions on updating in the manual, Support/Updates (Maintenance Releases). To determine which revision you have, click Help in the main program window, then About EZNEC. I strongly recommend that v. 5.0 users periodically check for updates.

The Forrestal disaster was attributed to druggies. The enemy was no doubt there on board. Many people have yet to figure out about the mechanics of such disasters. I submit that there will be 2 sides to every story to come out of the Vietnam war, and that sufficient truth is often left out to allow that.

I wrecked a few cars before I learned how to drive. Have you ever been tortured for information? or just for the hell of it? People who sit around and talk about it over tea aren't fit to judge who a hero is but they are often left to talk about it. Let's just call him "experienced". I really don't consider Obama to be the "Black Messiah" either.

I feel that both candidates were potential disasters, showing the idiots had prevailed before the election. The vote only served as an international "poll" on how best to proceed to our doom. It seems the election has tried to set the clock back to what it was before 9/11. Let's see what develops this time around.

I am intellectual enough to recognize something I have never taken an interest in. I am intellectual enough to recognize something I have never read on, engaged in discussion upon, and things which invoke and evoke emotions to cloud the participants into a "religious fervor", willing to guard and defend their own political beliefs.

And, finally, I am intellectual to recognize something which I have no intellectual interest in ...

Now, all that said, it would surprise me if one had ALL the facts, data and knowledge of the evil done, that the KGB should appear any more evil than the CIA or other related and/or secret arms of their and/or our governments ... my blind belief that men in power would honor their duties and responsibilities to the American people has been destroyed.

The time when our nation stood on infallible principals, morals, ethics, honors and commitments has slowly disappeared until such territories are loath to intellectuals--other than to demand a return to sanity, truth in government and the publics right to know, and a fair and just system.

Idiots will see little problem jumping into this quagmire.

P.S. Any of the following, and all, definitions of quagmire will do:

1. an area of miry or boggy ground whose surface yields under the tread; a bog.
2. a situation from which extrication is very difficult: a quagmire of financial indebtedness.
3. anything soft or flabby.

Or, intellectuals can tell when an argument or discussion is worth having; for the rest, there is always Rush Limbaugh.

Regards,
JS

You are correct. The demo is exactly the same as the standard EZNEC program except for the segment limitation. But I recommend using the current demo program rather than an older version or revision. Demo programs can be updated at any time by downloading and installing the current demo from http://eznec.com/demoinfo.htm. The old program can be uninstalled first if desired; otherwise the new one will overwrite the old one. This process won't harm any saved description files.

That's not a very good description, although it's correct. You can separate a circularly polarized field into vertically and horizontally polarized components, the sum of which is the circularly polarized field. And if you do that, you'll find that the two components are 90 degrees out of phase with each other.

But here's a little more complete description: The electric (E) field of a horizontally polarized wave is horizontal, and the E field of a vertically polarized wave is vertical. But the E field of a circularly polarized wave rotates at the transmission frequency, one revolution per cycle. The instantaneous amplitude of a vertically or horizontally polarized field is sinusoidal, varying at the transmission frequency. The amplitude of a circularly polarized wave is constant.

This is actually where I have stood since the first grade. Except that the public seems to have abdicated it's right to know by entrusting that to advertisers and spokesman.

1. Vote no when there is too much verbiage in legislation
2. Vote such that politicians will tend wear themselves out (on each other) before doing harm which often results from an unchallenged decision. This also gives the public more of a swing vote in their decisions.

The only infallible is God. Our country takes a tumble every time we lose our moral compass. Aside from that, NO country or system has ever been infallible. We could be disappointed under any system that we entrust all power to men (or women). Be very afraid when they are all in complete agreement, because they won't need us for anything anymore.

Along the way, though college, it is pointed out to you that any great story (or, at least a believable one) has a protagonist and an antagonist (sometimes more of them, sometimes less of them); i.e. a "good guy" and a "bad guy." It is based on a storyline where great adversity is found, great sacrifice and energy extended and exerted, and finally the defeat of the enemy is had ... funny, but we will fall for this same line though uncounted books by uncounted authors. Read any great Greek tragedies/novels/plays, Shakespeare knew this and you find it in his offerings. (Or, turn on Rush, "... bad democrats, good republicans ...", this is simply recited over-and-over again to keep idiots in line and massage the weak minds into the hypnotic/religious lies which got us here ... some still have futures which hinge on keeping the insanity alive. Indeed, real change will bring collapse ...)

Such is also how our political system is arranged, good guy vs. bad guy (and, you just pick who is good and who is bad, or toss a coin. Or have you allegiances bought and paid for ...) And, so is our foreign policy applied, we are the good guy, they are the bad guy and these are our friends who help us in our great adventure ... fear gets the whole ball rolling, even unjustified fear(s) will work ...

Someday, all will see the truth, become ashamed of living such a shallow "truth(s)", and be shamed into higher standards and goals ... until that time, a few can control the minds of many ... and ultimately the world.

I'm intrigued by this, and would like to know what "theory" it's based on.

The field radiated from a conductor is proportional to the current on it. You'll see from either modeling or measurement that the currents on all sections of a collinear array, or a long wire antenna for that matter, are nearly the same. So in those directions in which the fields reinforce, each section is contributing about the same amount to the total field as any other.

Although the logic is sound for this particular situation, it can't be used in general to assign particular amounts of radiated power to particular parts of an antenna. The fields from two parts of the antenna might partially or fully cancel in some directions, even though both are producing large fields. Any part of the antenna which is carrying current is involved in the radiation process, and the total field is the vector, not algebraic, sum of those fields.

So if you have a valid method of determining how much of the total radiated power comes from each part of an antenna, I'd be very interested in learning more about it. References would be welcome.

I had considered the "good cop", "bad cop" routine, but I really think it goes back to the "demoralization" and "destabilization" process that you yourself (and myself) admit to in lost faith, but healthy distrust along with a sense of reality is vital, but not to the point of being crippled.

Rush noticed that what's "good" for the Country is "bad" for the democrats and what's "bad" for the Country is "good" for the democrats. It isn't lost on me that "when it bleeds it leads". Who for example is responsible for those who apply psychological pressure to "known" gun owners to induce them to random mass murder? Who would that benefit? There are many cynical people out there with a sick sense of humor. Your assertion that real change would bring collapse is too cynical and I wouldn't set myself up to be wrong unless there is a complete failure. That just gives us the wrong goal. Seek God. I know you hate "religion" but rather than seeking as a blind follower, seek as a researcher. Set those things aside that you don't immediately understand but don't entirely dismiss them. That is simply arrogance. The intellectual is a fathead who completely dismisses that which he doesn't understand or what is related to him by the unschooled. Those who do that operate contrary to the scientific method. Even a failed experiment shouldn't be thrown out, but learned from. Or saved until the failure is understood.

In light of that, "The Interview" link I posted earlier, the true threat is the cynicism that developed that whole school of thought. It is a process of destruction. Not only that, but of unchecked destruction.

I just knew this would create a problem. I'm open to corrections and
explanations. I'm still learning and tend to make some rather
disgusting fundamental errors.

It's an observation based upon my measurements with a field strength
meter on similar UHF colinear antennas (using 1/2 wave stubs for
phasing). Also on a center fed 2.4GHz Franklin sector antenna of
similar construction. Most of the voltage peaks were at the base of
the antenna, tapering off as the field strength meter was dragged to
the top of the antenna. Since the current through the antenna is
constant, I assumed that the bulk of the power came from the lower
elements of the antenna. My explanation was a geometric decrease in
radiatated power starting at the feed point.

I've also seen a similar effect with relatively high gain (>10dbi)
2.4GHz omni antennas in WISP applications. Any blockage of the lower
sections of the antenna, had a much bigger effect on the range and
measure signal strength than covering roughly an equal amount near the
top of the antenna.

I can see that on some models. I never could successfully model an
antenna using coax cable sections as elements. Using a wire model,

the current distribution is constant along the length as you describe. However, my field strength measurements show more RF towards the feed point. It's difficult for me to tell exactly how much more RF because my home made meter is not calibrated. I don't recall the exact numbers but I can dig out the FSM and make some measurements on some of the antennas I have hanging around on the roof this weekend.

The models all show the total pattern produced by all the elements combined. I haven't found a way to show the contributions by individual elements, thus making it difficult to model my observation.

>So if you have a valid method of determining how much of the total

Nope. I'll give in easily on this one as it's highly likely I'm wrong. However, I will double check my measurements on the roof tomorrow and see if they're reproducible. I may have simply goofed and/or drawn the wrong conclusion.

Incidentally, I've been offering this observation for several years and you are the first to question it.

"What is good for the country" is a religious term, the way it is being
used lacks any real meaning ...

"The country" is its' citizens. It is not the buildings, it is not the
wealth, it is not plots of dirt ... when our public servants carry out
the majority of the people wills, while preventing great harm to
minorities, it is doing its' job. Government was created to serve the
people. It was never created to be an institution of "leaders" who set
policy, define monetary systems, influence the people, etc. It was
created to provide what the people requested, it is ONLY a tool which is
only valid when it is suffer-able to the people.

Government does a good job when it provides public transportation
systems, public roads, public sewer system, public water supplies,
public electric/gas/heating/etc. Public schools with high standards,
and those standards controlled by the people, is a good thing. Public

health is another good example, it protects us from ill individuals who are threats to innocents lives. You get the point--only involved in things which provide equal services/protections to EACH-AND-EVERY-SINGLE citizen.

Government does NOT do its' job when it takes religions marriage and redefines it for a minority which break the very meaning of the word (indeed, it breaks the separation of church and states powers from the get-go ...)

What is "good for the country" is good for ALL peoples (poor, rich, educated, uneducated, white, black, young, old, etc.), what is good for a minority is NOT good for the country.

Government should be like toilet paper, it is appreciated by all and servers all equally well ... <grin>

There's quite a handful of potential problems with this:

1. You might have been in the near field. The relationship between field strength in the near field and the radiated far field is very complex. You can't determine the field in one based on measurements in the other.
2. If you're in the near field, the field strength you measure at a given point depends on the type of antenna used. In the far field, the field impedance (E/H) is a constant value, but not so in the near field. In various places in the near field, an antenna which responds more strongly to the E field (a "high impedance" antenna) will show higher readings where the field impedance is high, and lower where it's lower. In any case, the relationship between radiated field and local near field strength isn't simple.
3. The power applied to the antenna is radiated in all directions, although of course unequally. As I explained in my last posting, the total field is the vector sum of the fields from the individual parts of the antenna. Sampling near the antenna gives you no idea of how the fields sum at a distant point.
4. It's very difficult to make even roughly accurate measurements even at HF, let alone UHF or higher. One of several problems is that it's extremely difficult to decouple the feedline when an electrically small probe is used, so you end up not measuring what you think you are.

That's interesting, and I'd like to get some more information about it. Perhaps blocking the bottom had a greater effect on the pattern, moving the maximum away from the direction of the other end of the path?

Here's a model of a coax collinear, but using coax with unity velocity factor. This "Franklin" array model was created by Linley Gumm, K7HFD. Coaxial cable is modeled as a combination of transmission line model, to represent the inside of the coax, and a wire to represent the outside. The technique is described in the EZNEC manual. See "Coaxial Cable, Modeling" in the index. I've posted the EZNEC equivalent to http://eznec.com/misc/rraa/ as COAXVERT.EZ. The accompanying Antenna Notes file is also there as COAXVERT.txt.

I don't. I wanted a number to show how accurate the cut would need to
be if he wanted the minimum VSWR point to be accurate to within 1MHz.
I picked 1MHz because the tolerance is easily scaled to other
bandwidth and accuracy numbers. My main point was that a fixture of
some sort was necessary to obtain that level of accuracy.

Well, at 418MHz, one wavelength (electrical) is about 600 mm.
4 degrees is:
600 mm * 4/360 = 6.7 mm
Yeah, that's fairly loose and could be done with diagonal cutters and
a tape measure. Normally, I would punch the numbers into an NEC
model, but I couldn't figure out how to model a radiating coax cable
section as an antenna element (using 4NEC2). I sorta faked it with
wire segments, but got stumped on what to do with the dielectric and
it's velocity factor.

Here's one way to build a coax cable colinear (for 2.4GHz):
<http://www.nodomainname.co.uk/Omnicolinear/2-4collinear.htm>
Note the measurements in Fig 1 for where to measure the half

wavelength sections. I'm suspicious. Of course, at 418MHz, it's less
critical.

>Using foam-
>Teflon coax makes it easy to do: the insulation doesn't melt when you
>solder things together.

I've only played with the RG6/u CATV flavor, where everything is
crimped. I never have tried to solder the stuff.

RG8/u with foam teflon dielectric:
<http://www.westpenn-cdt.com/pdfs/coaxial_spec_pdfs/50%20ohm%20cables/25810.pdf>
Looks nice.

I hate to admit that I made a mistake, but as you and Roy Lewallen
point out, my explanation of how this antenna operates is almost
certainly wrong. I'll do a fast measurement tomorrow to satisfy my
curiousity, but from your explanation and Roy's, I've erred big time.

With a constant current distribution along the length of the antenna,
and a constant voltage at the various feed points, it's a fair
conclusion that the power radiatated around each of these feed points
are equal. I goofed(tm).

That probably a good start. My testing was a 2.4GHz. My field
strength meter was just a shottky diode, balun, ferrite/choke
isolation, DC amp, and battery. Not very fancy and also not very
sensitive. I tried to calibrate it against a microwave oven leakage
meter, but go nowhere.

My guess is that I was about 20cm away from an 8dBi vertical in one
test. The antenna was a Tecom colinear. See omnis at:
<http://11junk.com/jeffl/antennas/tecom/>
I still have some of these antennas and plan to repeat my testing. At
2.4GHz, one wavelength is about 12.5 cm, so 20cm is well within the
near field. There was also a bunch of other antennas nearby, which
certainly contributed some reflections.

Umm... you lost me, but I'm not at my best right now. I'm in the last
2 weeks of radiation oncology. No problems but I currently fade
fairly fast in the late evening. I'll decode it all tomorrow.

>3. The power applied to the antenna is radiated in all directions,

>fields sum at a distant point.

Agreed, but I was trying to sample what was being radiated from a
single element (or antenna section). I could see some peaks and nulls
as I moved along the length of the antenna, so I assumed that I was
seeing the contributions of each section (at the peaks).

>4. It's very difficult to make even roughly accurate measurements even
>at HF, let alone UHF or higher. One of several problems is that it's

>probe is used, so you end up not measuring what you think you are.

I know. My meter is battery operated and made to be viewed with
binoculars. I've used it to measure the total pattern on several
antennas by hoisting it up and down a fiberglass pole (or wood barn)
without any connecting wires. The problems are that it takes 2 people
to operate (the 2nd to watch the meter in the binoculars). The
contraption is also slightly directional, adding some additional
errors. However, the big problem is that its sensitivity absolutely
sucks. I need something better. I've tried to modify a Wi-Fi finder
to act as a signal strength meter. That's more sensitive and works
better but has a miserable 30dB(?) dynamic range. This is on the
things to do list (after 100 other unfinished projects).

>
>That's interesting, and I'd like to get some more information about it.
>Perhaps blocking the bottom had a greater effect on the pattern, moving
>the maximum away from the direction of the other end of the path?

Ummm... I wasn't really able to move the tower on which the antenna
was mounted. The problem was that I was stuck on the lower part of a
rooftop tower. On the roof was also a parapet and HVAC box that
blocked the downward view. The antenna was an overkill 12dBi
something (forgot model numbers) omni. The antenna was about 3 meters
from the parapet. We have a customer that was in the shadow area.
From his window, we could see the top half of the antenna, but not the
bottom. We installed an indoor dish antenna, but the office
aesthetics committee vetoed the installation. So, I raise the base of
the antenna, so that more of the bottom of the antenna was visible.
The problem with this was that the top part of the antenna was in the
middle of a latticework tower section used as a horizontal antenna
mounting arm. The upper 25 cm of the antenna was fairly well covered.
Yet, the improvement at the customers was both dramatic and adequate.
I left it that way for about 2 months. When the weather improved, I
replaced the antenna with a lower gain 8dBi omni, which improved the
signal even more. A month later, I installed two 120 degree Superpass
sector antennas (forgot exact model number), with some downtilt, and
the single increased yet again. My guess(tm) was that the effects of
covering the lower part of the original antenna was greater than
covering approximately the same amount at the top of the same antenna.
Maybe not.

>Here's a model of a coax collinear, but using coax with unity velocity
>factor. This "Franklin" array model was created by Linley Gumm, K7HFD.
>Coaxial cable is modeled as a combination of transmission line model, to

>The technique is described in the EZNEC manual. See "Coaxial Cable,
>Modeling" in the index. I've posted the EZNEC equivalent to
>http://eznec.com/misc/rraa/ as COAXVERT.EZ. The accompanying Antenna
>Notes file is also there as COAXVERT.txt.

Nice and thanks. Forgive my use of a different modeling program but
it's one I know well, while EZNEC 5.1 is still somewhat of a mystery
to me. I converted the EZ file to NEC and ran the model without
modification. See:
<http://11junk.com/jeffl/antennas/CoaxVert/>
The geometry JPG shows the current distribution, which is as you
indicated, uniform. So much for my geometric decrease theory.

I'll play with it some more later. I don't really understand the TL
card, but will do some RTFM to see what I missed. 4NEC2 complained
about wire radius ratios, but I'll fix that tomorrow. I also want to
add a frequency sweep and move the design to UHF.

>I've seen models using coax with VF = 0.82 having a good pattern.

Well, if the OP builds it with copper tubing, PTFE insulators, and air
dielectric, he can use a velocity factor = 1.0.

So thanks all for replies. Wikipedia at this page
http://en.wikipedia.org/wiki/Circular_polarization show more, and now i have
also clear in mind the fact that circular polarization is first made by a
physical, circular design of dhe radiant element and i can also have
clockwise or counterclockwise sense of the polarization.

By the way, due to wavelenght we are playing in the HF, i doubt that can be
realized a true circular polarization antenna for HF spectrum. Maybe
something can be realized on VHF and up.
Merely theory dreams in my mind, as in the real life i'm working HF with a
couple of butterfly dipoles covering from 80 to 10 m... :)

Thanks anyway to pay me attention.

Message-ID: <49315526$0$20307$607ed4bc@cv.net>
Source record: 19687

I have the 30/40 add-on for a 3-element SteppIR. Seems to work well. However, the middle element (a double element with a "U" fitting at each end) droops more that the two simple elements. This probably does not affect the operation of the antenna, but it looks odd.

I have been thinking about extending the mast a few feet (probably with PVC) and using dacron rope from the mast to the ends of the middle element, to give a little more vertical support. However, unless the mast extension is rather long, there would be a substantial horizontal force pulling the ends of the element toward the center.

Has anyone done something about the drooping center element?

I agree. My experience is that:

1. It's difficult to generate circular polarization in more than two opposite directions at HF. With something like crossed dipoles fed in quadrature (sometimes called a turnstile), the polarization is circular only at right angles to the plane of the dipoles. It's linear to the sides and elliptical elsewhere.
2. Even after you generate a circularly polarized signal, ground reflection tends to make it linear. It's difficult or impossible to avoid ground reflection over an HF path.

Hi Roy

Just for conversation, I submit that an antenna with good hemispheric CP
coverage could be made with 4 dipoles.

My model has 120 0.5 wavelength radials buried 1.2 feet deep (the unusual depth due to rescaling another model). Ground conductivity 8 mS/m, dielectric constant 13. The antenna is 0.25 wavelength high. The whole structure is made from #12 wire to eliminate any problems due to dissimilar diameters. Field strength is Ez at 1000 meters with 1000 watts applied.

Using the NEC-4D calculating engine, EZNEC Pro/4 shows (NF = near field analysis, GW = far field analysis with ground wave):

Z = 40.08 + j27.91
GW = 297.7 mV/m
NF = 297.7 mV/m

Same, but with 0.25 wavelength radials:

Z = 39.56 + j26.55
GW = 292.7 mV/m
NF = 292.7 mV/m

Note that the feedpoint R and field strength don't exactly correlate if you make the assumption that the resistance difference is due to loss. This would be due to a slightly different current distribution on the radiator due to interaction with the different ground fields. Other experiments have shown that the impedance will also vary some with radial burial depth.

Following are the results using the NEC-2D engine with a 0.25 wavelength vertical and 120 0.5 wavelength radials one foot above the ground, all other conditions otherwise the same. This analysis can be run with EZNEC+, but only the NF results will be available:

Z = 66.83 + j1.894
GW = 230.0
NF = 229.7

As above, but 0.25 wavelength radials:

Z = 32.42 + j18.87
GW = 311.4
NF = 311.4

Elevated radials, even when elevated only this amount, show distinct resonance effects, and making them longer than about 0.25 wavelength often results in reduced efficiency which I think is due to movement of the radial current maxima away from the center. The above results illustrate these phenomena. While slightly elevated radials can be used to approximate buried ones, as you can see the substitution isn't perfect.

The same 0.25 wavelength vertical over perfectly conducting (or MININEC) ground showed a Z of 37.95 + j21.49 ohms. However, the resistances of the various examples above aren't just this resistance plus loss resistance, since the current distribution isn't quite the same when radials are present.

The results you got weren't valid due to use of MININEC ground with near field analysis, as I explained in another posting. As you can see, you can get reasonably good results using EZNEC+ and near field analysis, although the vast majority of people this intensely interested in the mechanisms of AM broadcasting aren't hobbyists but rather professional engineers who are using EZNEC Pro/4.

Yes, there's the quadrifilar helix which I believe fits that description. Another, which I built decades ago at 450 MHz, is the "skew planar" antenna which resembles a cloverleaf but with the "leaves" rotated 45 degrees. Although I haven't seen either one constructed at HF, on reflection I don't see any reason you couldn't.

There's still the problem of ground reflection, though. I didn't state it very well in my last posting -- what I meant was that the sum of the direct and ground-reflected rays tend to produce a linearly or nearly linearly polarized wave even when you start out circular.

Hi Roy

I say with some humor - Have you considered the DCA as described in the
Feb2008 QST? For most conditions the DCA performs better than a
quadrafilar helix and it is much easier to construct.

Thanks very much for your numbers and comments, Roy.

I would never have thought to try to use EZNEC near-field analysis to compute the groundwave if I hadn't read the suggestion to do so in this thread. That was my first, and will be my last attempt at that.

When I need to calculate the MW ground wave for a particular distance, monopole height, frequency and ground conductivity I use the FCC method of first determining the inverse distance field of the radiator at 1 km for 1 kW of radiated power, and then using that value in a program I have with the FCC's MW propagation curves in digitized form.

My point when starting this thread was to show that the elevation pattern radiation actually launched by vertical monopoles on any frequency does not have a zero/very low relative amplitude at/near the horizontal plane, which from what I read on these NGs seems to be a popular belief.

The conversation reminds me, in 1947, I lived in Dayton, OH. Not far from Columbus, OH and the home of Kraus. He was the guest speaker one evening at the Engineers club in Dayton and I attended. He did his usual trick, a 400 MHz tone modulated oscillator and a receiver, both with plain vanilla dipoles. Spaced across the audfitorium, he would hold up a piece of cardboard between the two and stop the signal. Then he hooked both to a pair of his helix antennas and tried but could not stop the signal. Of course, he had a Faraday shield between TWO layers of cardboard. Some, who had looked into his background more deeply than I, told him what he was doing. To me it was remarkable.

NOT more remarkable than a ham in Dayton, call unknown, who had erected a 4 turn square helix for 20 Meters at his home in honor of the occasion. Made of Aluminum downspout pipe, 16 foot on a side, complete with reflector of chicken wire and supported on a long length of 2 x 4. Before the days of CDR, but rotated with a prop pitch motor. I'm not certain of what the neighbors thought of it, but it sure looked impressive to me at age 22.

Have you ever tried to get a clear picture, "next to the TV transmitter station"? The radiation pattern on the transmitting antenna leaves almost no signal in the shadow of the tower. I had to point the OTA antenna towards another tower a half mile away to get enough signal to monitor the 5 MW EIRP signal at the Channel 55 tower in Orange City, Florida. People within a half mile of the tower base couldn't get a clear signal.

I've suggested it to you on at least one of the several occasions you've brought this subject up, in the thread "Re:Rhombics" on Oct. 1, 2006. I've also mentioned it at least 10 other times on this newsgroup going back as far as 1998. Reg used to entertain himself by periodically complaining about EZNEC's lack of ground wave analysis, and most of those postings mentioning the near field technique were in response to his postings. I see you've taken on that aspect of Reg's former source of entertainment. You and Reg were just about the only hobbyists who have this intense interest in EZNEC and ground wave analysis, and now that Reg is gone it's pretty much down to you. Of course you could directly get the results you want from NEC-2, which is free and readily available. I assume the reason you don't simply do that is that it wouldn't be as amusing.

> When I need to calculate the MW ground wave for a particular distance,

Since you can use this method to get results you believe to be correct, why do you need EZNEC? If you want another program to give you the same answers, why not use NEC-2? NEC uses the same method as the one used to generate the FCC's curves. But I believe the FCC curves account for Earth curvature while NEC doesn't, so I'm told they begin deviating at somewhere around a couple of hundred miles.

I don't believe I've ever read that. But if anyone does believe it, a much larger number believe just about the opposite -- that the signal strength from a vertical is maximum at zero elevation angle at great distances from the antenna. This of course comes from the ubiquitous plots of the pattern of a vertical over perfect ground.

Guess that's enough for now. Maybe you can go a little longer before bringing it up again the next time? In the meantime, I suggest you either update your v. 4.0 EZNEC demo program or replace it with v. 5.0. The demo programs are still free.

Excel is a notoriously bad thing to use for statistics or numerical
analysis. Aside from the pain the rear nature once you get past
trivial manipulations, there are some serious calculation issues to
worry about (since Excel isn't rigorously tested for its
implementation, these also change as versions change)

http://www.burns-stat.com/pages/Tutor/spreadsheet_addiction.html
covers a lot of the problems.

You're better off biting the bullet and using something like Matlab
(academic license $100) or Octave (free, but not quite as fancy as
Matlab, but mostly compatible) or similar products.

No.. it's that a significant part of IEEE's budget derives from publishing copyrighted standards and journals. One argument for the copyrighting of standards is that it provides a legal club to go after someone publishing an adulterated version. I'm not sure that really holds water, but there it is.
The cost of actually printing the journals is significant, and has to come from somewhere. They're not exactly huge circulation, and mostly have no advertising, but are printed on high quality stock with good quality typesetting.

> This statement was in regard to the high costs of obtaining copies

The cost to get a single copy is quite high compared to the cost to get access to thousands by being a member (check out those CCC prices at the bottom of the first page.. they're fairly pricey.. a dozen papers a year and you've just paid for your membership and access to Xplore)

I understand the need for
> peer review by academics but not necessarily a private entity
> and the IEEE rights to publish such so, are the IEEE demanding SOLE
> ownership of presented papers?

IEEE performs a useful function by organizing all those peer reviewers (finding them, getting the papers to them, haranguing them for their reviews, etc.).. Being an editor is a lot of work, and is often done as a labor of love by the editor (or, as "part of your job" in academe), as is being a decent reviewer. IEEE requests copyright transfer to them for papers published in their journals for a variety of reasons, and with a variety of exceptions.
1) Makes sure that you're not publishing the same thing in multiple places at the same time..
2) If your work was done, e.g., on gov't contract, often, the contract requires that the paper be public domain, and the IEEE is cool with that.
3) The author can publish the paper on their own website with an

appropriate disclaimer.

> I am assuming that all papers presented by the Universities as well as
> thesis papers belong to the parent university

> a student dissertation.

Not necessarily ("all" is pretty all-encompassing).. A lot depends on
the funding source for the work.

This leaves
> an outstanding question !. If the university a public entity,
> reserves the rights of all papers arrived at the university
> then what rights do they hold that allows transference from the public
> domain of those rights to a private institution to the detriment of
> the public
> that finance them?

Those rights were never in the public domain to begin with. One might
argue that the underlying idea is in the public domain, but the
written description of has a copyright that belongs to the author
(except for a "work for hire") and the author gets to decide what they
do with it. And, I would argue that arranging for the publication of
the work in a "learned journal" is a pretty effective way of
disseminating the work to the general public. The fact that IEEE (or
Inst of Physics or AAAS, etc.) get an assignment of copyright as part
of the process is part of the cost of doing that publication. And
it's a fact that as online publication becomes easier, work IS being
disseminated by these means.

However, one should not disregard the significant value brought to the
process by the formalized peer review system. Yes, it has flaws and
can be (and has been) subverted, but it works moderately well.

Compare to the situation a hundred or two hundred years ago. I don't
complain that "the system" isn't moving as rapidly as technology might
allow, because the system has a fairly long time constant, which is
actually a good thing, since it prevents rapid whipsawing to follow
fashion. A printed journal will still be readable 100 or 200 years
from now. The same cannot necessarily be said of djvu or pdf or tiff
or other elecronic forms.

One should also not complain too loudly about the lack of heritage
journals on line for free. It costs a LOT to scan thing and put them
online, particularly if they're searchable. If you could convince
Congress to do it as a service to mankind, that would be a worthy
goal, but for now, someone's got to pay for it.

If the paper is under the auspices of the University it belongs to the
University.Period
Same goes for doctorate dissertations plus patent rights if applicable
to disertations.
Since it is a public University I question their rights to with hold
information
from the public at large. This is a great inconvenience to those laid
off,
unemployed that wish to stay up to date while searching for
employment.
To with hold information from the general public can be seen as a
crime against the Country
and there are other ways of obtaining reviews without non revealment
to the public.
Universities already prevent online useage of their technical
libraries but there is not one good reason why
studies paid for by the public taxes should not be placed on the
INTERNET.
To deprive the unemployed, retired, teachers and those under license
by federal authorities in pursuit of
science advancement is a crime against the Country by denying it a
path to a better society.
If there is a need for overview by one's peers then Universities and
education bodies should be able
to handle things for themselves instead providing papers to a private
institution for personal benefits.
It is time for CHANGE in the US where the ability for its people to
access any means that is to the
countries benefit as well as it constituents.If a patent holder or
applicant has no rights with regard to dissemination of his studies
then there is no real need for concealment by public entities
When public papers are handled by those elected by the people the
present professional bodies will have to allow the market to decide
whether there is a place for them
I suppose eventually there will be a request in federal court that
such information must be released for the press or the publiwhich can
be hastened by
informing your Congressman or Senator of the

THEFT OF PUBLIC FUNDS
BY PRIVATE ENTITIES

Roy:

Don't _you_ believe that the results I posted using the FCC method I described to be "correct?"

Regardless, and to answer your question -- I don't really need EZNEC. But it can be interesting to see how various analytic methods compare.

Quite a few years ago and after due investigation/consideration, I paid about $300 for the NEC-2 products of one of EZNEC's competitors, because I preferred its graphical output choices and print quality, its higher segment limit compared to EZNEC+, and the customization it allowed in its printed output legends. This capability included the synthesis and import into the NEC model of any one of many dozens of 2-D and 3-D structures, to their specific mechanical specifications defined by the NEC user.

The main reason I use EZNEC occasionally is to investigate the claims of others who use EZNEC.

Sorry to be blunt , Roy, but then you asked.

?? My reading of these NGs shows that many/most amateur radio operators ignore/discount the fact that the peak radiation launched by a vertical monopole of 5/8 lambda or less in height ALWAYS occurs in the horizontal plane., regardless of the operating frequency, or the r-f ground in use.

The radiation/reception characteristics at low elevation angles of such an antenna can be useful in establishing contacts with the most distant possible single-hop DX sites, can they not?

I don't think most amateurs care about the locally launched radiation, except when dealing with local RFI. That low angle radiation decays to essentially nothing within a few miles at HF and even less at VHF and above. So it's of no use for communicating beyond a few miles.

> The radiation/reception characteristics at low elevation angles of
> such an antenna can be useful in establishing contacts with the most

They can not. I see you're still a bit confused about what happens to that ground wave signal. Beyond a few miles at HF, that low angle radiation decays to essentially zero. The pattern of the field beyond that distance resembles the one reported by EZNEC and other programs giving distant far field data. And they correctly show that unless the ground has very high conductivity at the reflection point, there will be very little field remaining at very low angles beyond that ground wave decay distance.

The performance of an antenna when communicating with a distant station is precisely what EZNEC is attempting to show you. If you want to know how it will do at various elevation angles for DX, or even at distances of a few hundred miles, look at those plots. At HF, ground wave analysis will only tell you how well the antenna will do when talking with someone across town. Which is why there's very little interest in ground wave analysis among amateurs, HF broadcasters, or just about anyone except AM broadcasters.

If you used an intermediary structure, you could eliminate/reduce
deformation of the element.

I can't engineer it for you but consider that you could have your Dacron
rope attached to another structure, perhaps more PVC, suspended above the
drooping element by rope loops on both sides, each supporting one side of
the (now no longer) drooping element. (A suspension bridge comes to mind,
in that the weight of the roadbed rests on the vertical suspension cables,
whose stresses are transferred in turn to the towers and the anchors.)

Just a thought

so go file a criminal complaint... even at 'public' universities not all research work is paid for by the public. many projects are funded by private companies and other entities who retain the right to such work and any patents that may result. now of course most patents are publicly available, but not all of them... go figure that one out. of course how much more are you willing to be taxed to support electronic publishing of everything written at a public university? that service doesn't come for free, and the sheer volume of that stuff would make it downright expensive.

if the parts are made by the original manuf, perhaps you should
contact them to see what they recomend to releive that droop,
and might even have a pre made solution, it's worth a email
to them at least

if they don't offer premade hardware perhaps they would at leas
suggest a solution that wouldn't unduly effect the antenna

I'm not considering that the ground wave signal _provides_ any of that low-angle DX coverage. It is the direct radiation existing in the radiation pattern of the monopole at low elevation angles that can do so. No ground reflection is necessary to create that field - it is launched by the monopole itself.

Below is a link to a clip from Terman's Radio Engineers Handbook, 1st edition, showing that the greatest single-hop range for skywave signals occurs from the radiation of the monopole at elevation angles of less than ten degrees. But looking at a NEC far-field analysis this would seem impossible, due to the greatly reduced fields in this sector that NEC shows for a vertical monopole over real earth.

This clip was done for MW frequencies, but the concept would apply equally at HF, would it not?

Any time you double-illuminate the far field you are creating lobes and
nulls. A single omnidirectional radiator is optimal for a moving
station, unless you have means to steer the lobes whilst steering the
vehicle.

They do look bad-ass, but just connect one of them and you'll have
better overall performance (theoretically).

I have asked the trusties what the policy is regarding this before I
proceed.
I am in the rujst belt and there are many engineers that have and are
going to be laid off.
They will not be able to afford to stay abreast of things and thus
will be hurtin the coming depression.
Not good for the Countries future I would say

hi

I wondered what would happen if lightning hit my station.
Realize that it's impossible to say exactly but in general i wonder
what the 'step' of failure would be ...

My set up is fairly simple:

I have a few J poles (stainless rods)
some dipoles around 80f some are 10ga some 14
a gps antenna
a fiberglass 900mhz and 1.2g

a 2m and 440 sat eggbeater

most are connected via lmr 400 some lmr600

preamps on the sat are cat 5 fed
one dipole has a sgc tuner fed also via cat5

straight run from roof down a concreate 2x3ft 'shaft' opens on
roof down to elec closet on my floor then into my apt

I have ICE lightning protectors (14story building i am on 4thfl)
almost near where coax enters my apt

they are 'grounded' to the elec ground which I tested and is good as
elec grounds go

typically when weather is bad i unscrew the coax going to the radios
at the ice and leave dangling this creates about a 2ft 'gap'

so assuming a worst case and my roof antennas take a direct hit

what would i theorize would happen?

I suspect the 14g dipole wire would vaporize perhaps also the 10ga

perhaps the jpole might remain?

i suspect the egg beaters would partially vaporize and their baluns
melt

the sgc would fail,

would the coax vaporize at the roof?

would i suspect (distance from roof to ICE @ apt 175ft of coax
) the coax would carry much power measured at my apt end? or
would it vaporize first??

if not would it be absorbed by the concreate walls given the distance? /arc? by the time it got to my apt?

assuming there would be power down to the ice and given it's connected to elec ground would anyone suspect they would dissipate the power to gnd? or just arc over the apt?

any general thoughts as to what might actually happen in this scenario from both a practical and theoritical would be appreciated

i always wonder what would be logical to assume in a direct hit scenario

thanks

I had a simiar case with a fibre glass tube of extremme length.
I injected insulated foam inside the tube and deflection was greatly
reduced.
This ofcourse is no substitute for securing a stiffener of a suitable
material to
the center length of the radiator

Maybe you should play it safe and use the "Lee Trevino one-iron" lightning protection club.
I believe it was Lee Trevino who started it - during a thuinderstorm, when lightning was hitting all around, the golfer pulled a one-iron out of his bag and held it up high saying that 'even God couldn't hit a one-iron'.
So wrap your coax around a one-iron and hope you've been a good boy.
:-)

If fed in phase and spaced correctly, there could be gain to the front and
to the back with a decreased propogation to the sides.
This is usually desirable if traveling on a mostly straight stretch of
highway. I think the spacing is a little too far apart for use on most cars.

The rule of thumb is things less that .1 wavelengths in size have
negligable effects, so roughly up to about 1 GHz.

I figure this is for an 18 wheeler on CB. In that case the dual
antennas make the patern more omni. Back in the 70s I belonged to a CB
club and we did some test of the effects of auto body styles on
radiation patterns. We discovered body stle and mounting location were
as important if not more so than the antena you were using.

An 18 wheeler with a single antenna mounted on a mirror has a really
ragged radiation pattern. Two antennas makes it a lot less ragged,
still a far way from being omni-directional.

Jimmie

Hello,

Thanks for replying Richard and Jim. I hoped somebody had a similar problem and knew a work-around. I know Excel is not the perfect tool to do this, but I did similar things with reasonable results. I hoped using data tables would speed up the spreadsheet design (until now it didn't).

I do not have OO.org installed on this machine. A brother in law has it on his PC, so when I visit him I will try to load the worksheet into OO calc (or set it up in OO calc).

When this (OO calc) doesn't give the desired result, I have to change to something that supports programming. I am not a student so Matlab might not be option. I looked at "octave", "python" and "R". These require some study also. Other option is to use an old general purpose SW development package (C or Pascal based).

I think I have to spend some time to decide what to use...

Best regards,

Hi Jim,

You neglect to mention that a 3 meter dish would be wholly (no pun intended) transparent to RF in the top band. It could be solid metal to no notice by a radiator (or receiver).

It would be like blocking the sound 3 feet from the stage at a Led Zepplin concert with a Japanese parasol. -Huh?-

Hi Wim,

After following Jim's link, and reading it to considerable depth, I
wouldn't trust Excel to do anything more than 3rd grade arithmetic.
Even then, there are too many examples to suggest I still could get
burned. Take heed of their cautions that "reasonable results" are not
always accurate results.

Could the financial meltdown be attributable to rounding errors in
spreadsheets?

Make the investment and go with R.

Yeah, I foolishly forgot the source of the question and assumed "top band" meant highest useable frequency.

Unless I hosed the math, a 3 m dish would be a little over 10 db isotropic at 2 m, so the combinatation would "work" from 2 m to 23 cm.

Cross-posted to: rec.radio.amateur.antenna,rec.radio.shortwave,misc.transport.trucking

I always wondered whether a short/loaded magbase antenna on the trailer roof (so it doesnt hit bridges etc) would work better than a mirror mount...

How much roof to bridge etc clearance is there normally?

I would have a thought a DDRR would have been good too but I read something recently that mentioned performance has never been as good as expected.

Thoughts?

Cheers Bob

I ask the question because the radiator is a helix end fed, helix
being approx 0.3 M diameter. Intuitively, I thought that the 3 M dish
would be large enough
and thus needed a check on the perforations. Could you show how the
"combination" changed things so drastically so I may benefit from the
question?

I stated "intuitively" since the radiation is axia with respect to the
helix
Many thanks
Art

NEC is not a propagation modeler.

However, resourcing the top engineers of the AM field for their
observations of sky-wave and ground-wave field strengths (a typical
service application) where they combine destructively (the "fading
wall"); at a distance of 70 miles, for 50% of the time, both signals
are equal (with propagation variations of phase accounting for
fading).

The graph you supply suggests that this 70 mile distance is obtained
by a launch angle (for the sky-wave) of 60 degrees. The NEC far-field
analysis for the BL&E antenna of 70 foot tall radiator in a field of
113 135 foot radials over average ground has a response of -2.32dB @
60ï¿½ and -1.61dB @ 1ï¿½ which shows a pretty close accord with field
reports from Laport (Fig 2.7).

Well, if you take the question literally, the aperature of a 3 meter
dish is ummm.... 3 meters. If he had said effective aperature, the
answer might be different.

As for top band (160 meters), he might be referring to a chicken wire
ground. This looks marginally applicable:
<http://lists.contesting.com/_topband/2002-09/msg00005.html>

Maybe he's thinking of burying his 3 meter dish and using it as a
ground radial system?

Incidentally, I've had rather bad luck using twisted galvanized chicken wire for making dish antennas. I kept getting intermittent noise crashes and arcing like noise bursts on a 1.7GHz WX satellite system I once threw together. I eventually found that banging on the chicken wire would produce the same noise bursts. I didn't bother trying to find out exactly what was doing the arcing. When I switched to using aluminum flashing and aluminum duct tape for the reflector, the noise went away.

I've read some reports that such is due to the poor contact of the
twists in chicken wire.

I suppose soldering all the twists would fix it.

A helix doesn't radiate in the axial mode unless the circumference is between about 0.75 and 1.33 wavelengths.

The would put the minimum frequency for a .3 m diameter helix at about 240 Mhz and the maximum frequency at about 420 Mhz.

Also, the reflector for a helix is a flat surface, not a dish, and is normally between about 0.8 to 1.1 wavelengths in diameter. If you make it larger, the sidelobe levels increase.

No, No, No. That is not correct. Just as Kraus over estimated the gain
of helix antennas he also made a mistake
in specifying a particular helix angle as well as the impression that
one needs a large diameter helix with reference to wave length.
Ofcourse his work is over 50 years old and is being wittled down with
futher investigation.
I modeled it against perfect ground as the latest papers state that a
wall around the bottom where there is maximum current provides best
gain.
Thus I see the deep and large diameter dish as being an equivalent.
If .1 WL is a rule of thumb then it would seem your first response is
correct.
That is my personal view but I am open to contradiction hopefully with
reasons why
Art

Yes, yes, yes, it is all corrct.

> Just as Kraus over estimated the gain
> of helix antennas he also made a mistake

Nothing was said about gain.

> in specifying a particular helix angle

Nothing was said about the helix angle.

> as well as the impression that
> one needs a large diameter helix with reference to wave length.

A circumferance of 0.75 to 1.33 wavelengths is required for radiation
in the axial mode.

> Ofcourse his work is over 50 years old and is being wittled down with

Nope; correctness has no expiration date.

> I modeled it against perfect ground

A pointless exercise.

> as the latest papers state that a
> wall around the bottom where there is maximum current provides best
> gain.

What papers are these; the ones from the outhouse?

A short "wall" around the outer edge of the reflector reduces side lobes.

> Thus I see the deep and large diameter dish as being an equivalent.

Most people would call that delusional.

> If .1 WL is a rule of thumb then it would seem your first response is
> correct.

Of course my first response was correct; things smaller than 0.1 wavelengths
can usually be ignored.

I for one, think you correct. What is "launched" at the antenna obeys physics laws at 100 ft., 1000 ft., 10,000 ft., 100,000 ft., 1,000,000 ft. ... the signal does not ever suffer magical, mystical, supernatural manipulations--EVER!

You don't mention what the roof antennas are mounted on.
IE: metal masts, vent pipes, etc?? Well grounded, or not?
If you are depending on the feedlines taking the brunt of the
strike to ground, yes, could be some damage along the way.
I doubt the dipoles would have much trouble, but the J-pole
could well take the strike. Or any other vertical pointy antennas.
That you are grounding at the entry will probably save the
house if you have a good low resistance ground at that point.

But it would be better to have the supporting antenna masts
take the brunt of the strike to ground via good ground wires
or straps if on the roof, or even better, directly planted on the
ground.
You will still have current on the feed lines, but it will be much
less than if they have to carry the whole load.
This is why I've always preferred using a stand alone metal
mast as my support. I'll mount my dipoles slightly lower than
the tip of the mast. Sometimes I'll have ground planes or
verticals on top, but if I do, I always run the coax all the way
down to the base of the mast before leading it to the shack.
I've had two strikes to that mast in the last few years and
had no damage at all. The mast acted as the lightning rod,
and the antennas just floated along for the ride.
I have the coax cables grounded outside the window, and
you can hear an audible arc at the instant of the strike.
So there is current on the lines to ground, but it's not enough
to hurt anything.
But if I used the coax as the only path to ground, I wouldn't
feel near as optimistic it would survive without damage.
And 175 ft is a pretty long path to take if it's not straight
down to ground. You want all those cables snubbed to
ground at a point well before they get to the ICE.
If they dangle from overhead down to the ICE, the potential
will be quite large.

That's because nobody has found a reason to want you to fail. There
can be many reasons for this. Optimistically, you have a well managed
company, that keeps people in positions where they are best suited.
That's rather rare as most companies will follow the Peter's Principle
method of promotion (rise to your level of incompetence).

Another possibility is that you have successfully eliminated any and
all competition for your position, thus making find a replacement
impossible. Unless you have a suitable replacement trained and
waiting, most companies will not your promotion to create vacuum.

In some companies, a promotion is tracked by a raise in salary and
benefits. In some countries and companies, it's actually impossible
to get a raise without a change of title. Perhaps your company needs
to manufacture a suitable position and title for your promotion? Note:
Assassinating your boss is not a viable option.

It's also possible that you have hit the glass ceiling, where
promotion is no longer possible. For example, many family owned
companies will not promote non-family members beyond a certain point.
If you're the wrong race, religion, sex, age, or nationality, you will
have problems getting a promotion. Same with failing to join the
correct country club, attending semi-mandatory social occasions,
wearing the wrong style clothes, attending the wrong church, and
generally sticking out like a sore thumb. Conformity pays well.

It's conceivable that you also lack sufficient initiative to obtain a
promotion. Many managers assume that someone that keeps their mouth
shut, does not need a promotion. Leaving your resume floating around
your desk is great way to either indicate that it's time to move up or
move out. Unfortunately, it can also get you fired, so use this trick
sparingly.

Anyway, if you need advice on what NOT to do in order to get promoted,
I have a long list of personal experiences that eventually inspired me
to become self-employed. I can't say that it was the right decision
from the financial point of view. However, I can say that I probably
saved a few companies from self destruction by removing myself from
their management structure.

My best friend H B Mutter N3CBW had a position of one of three
military top judges
where he was on call for any major criminal case which could involve
the maximum
sentence. However as a Judge he had his own ideas of morality that
sometimes clashed
with beaucrasy but he always held to his guns which is why I respected
him so much.
Eventually he was offered a generous retirement based on a perceived
malady, so in the end he won.
This was the only way out available to beaurocracy, the common man
does not have such leverage
and is blown away. He now lies at Arlington cemetary bless his soul, I
miss him so much

Not much on a big truck.
Since most of the usable cophased signal is blocked by the cab and
trailer. I've found a single antenna works just as good.

What hurts the system the most, is the factory installed crap.
They generally use the smaller 75ohm cable and use splice after splice
to make it work. I generally get my own cable, bypass their stuff.

One thing to remember in cophasing, cable length DOES make a
difference. If they are not equal, things will be out of whack. Unlike
in a single antenna where length is not an issue.

Oh and for all you loudmouths out there, the only reason they say you
must have x amount of feet, is to sell the damn cable.

In reality, the shorter the cable, the better off you are.

Have you held an FCC license for radio work?
I have.

I am aware of that. One person once said the world was round!

If one was persuasive enough at the beginninghundred years or so later
if one said
the world was flat he would be called delusional.
If one was very persuasive in the first place he would be rediculed as
it was so obvious to all in the first place.
I hope you get to live another hundred years so that you can meld into
the new crowd of lemmings

Just a few years ago i could get physical reprints of articles from
most journals for about $3 each, now electronic reprints cost $20 or
more? I think we all can figure out where the money is going.

Funny thing about "work for hire", the hiring entity is the one with
any legal rights here in the US. But the NIH for some strange reason
does not assert its rights. The IEEE does not publish work for hire
generally, but charges for submissions.

> And, I would argue that arranging for the publication of

Yes, but more an more by others, and the academic journals reviewers
are not paid. The other publishers do not do the review so quality
suffers. The old school publishers need to learn that they cannot
just take it all.

I am not so sure about that. The need for preservable media is being
recognized. It has even been discussed in learned journals.

Since the feed point impedance of most of those antennas is really way
less than 50 ohms 75 ohm cable may not be the best choice to make a
phaasing harness. Most of the time 50 ohm cable works better

Spoke to my son about this subject as he works for a California
University.
He states that this subject is on a unstoppable role in several states
because of diminishing distribution of papers.
Together with high costs for separate papers that is also diminishing
in demand.and was a money maker
(As jobs are lost so goes the membership costs I suppose)
He said that some Universities are already changing from the old set
up and google is being very agressive about it.
Apparently there is already a group on the net with connections to all
phases of science where you can obtain a
UNPUBLISHED paper for a modest fee so there are new avenues emerging.
Haven't got a policy statement from the local trustees at Champaign
Illinois as yet.

Regards
Art

I believe you're correct. This is a "broadside array" configuration.

Its gain over a single radiator rises roughly linearly (measured in dB over a single radiator) up to separations of around 5/8 wavelength. A separation of 1/2 wavelength gives around 4 dB gain over a single radiator and a very nice clean pattern (deep null to the sides) - this is the spacing most frequently described in the literature (e.g. Kraus, Terman) for broadside arrays. Gain maxes out at just under 5 dB at a 5/8-wavelength spacing (at the cost of a small side-lobe). [Figures are from the ARRL Antenna Book of a few years ago]

Whether it's worth doing for a vehicle-mobile system is another question. You need more than .4 wavelengths of separation to get 3 dB of gain (half a nominal S-unit) - at 11-meter frequencies that's around 14 feet of separation, which I think not many vehicles will allow. Perhaps if you're driving a "wide load" transporter truck?

At 6 feet of separation between antennas you'd have only around .2 wavelength, which yields less than 1 dB of gain over a single radiator. Hardly seems cost-effective.

It might make more sense for 2-meter operation... but as most 2-meter mobile seems to be repeater-based, you really want omni rather than shaped-beam-down-the-road most of the time.

There's also the matching issue. Each radiator in the array will have a feedpoint impedance different than what would have if used alone. You'll have to take this into account when designing the phasing harness, and you may need an impedance-matching network at the combining point to establish the 50-ohm load that your transceiver expects. If you don't match properly your transceiver won't see the load it expects, and may not deliver full rated power into the load - you could easily lose more signal strength this way than the array will gain back. If you do match properly, there will be some amount of loss in the matching network.

There ain't no free lunch, alas.

Art wrote:
"I stated "intuitively" since the radiation is axia with respect to the helix."

A 3 M diameter has about 9.42 M circumference so becomes an effective axial radiator instead of a radial radiator at the frequency near where its circumference becomes one wavelength. This frequency is 300/(pi)(diameter) or about 10 MHz. A reflecting surface to make an axial helix unidirectional needs to be at least as large as the projection of the helix on the surface of the reflector. Its diameter should then be about 3 M or more and would be effective only at frequencies exceeding 10 MHz which is where the helix becomes an end-fire device anyway.

Best regards, Richard Harrison, KB5WZI

Radiation from the monopole from zero to 10 degree elevation is not "poorer by 12 dB" than that launched at 40 degrees. It is greater.

The _reception_ of such radiation is a different matter, as the total, skywave path length, and therefore the propagation losses are different for those elevation sectors. This accounts for the lower value of received field at the greater distances, as shown in Terman's Fig 55.

You can write plug-ins for Gnumeric in Python. However, it's best to
run Gnumeric on Linux (or another Unix of your choice). There is
Windows version, but unfortunately, it is somewhat unstable.

> fading).

With more research you'll find that the fading zone is not located a fixed 70 miles away from every AM station.

The fading zone occurs wherever the skywave and groundwave are approximately equal, and that varies with frequency, the elevation pattern of the monopole, the conductivity of the groundwave path, and the altitude of the ionosphere.

Most Class A (50 kW, non-directional day & night) AM broadcast stations use a monopole of about 195 degrees in height, as this extends the groundwave coverage radius over that of a 90 degree monopole without generating a substantial high-angle lobe to interfere with the groundwave where it otherwise would have a useful value.

Where substantial skywave signals are present from a ~195 degree radiator, the groundwave already has been attenuated by propagation loss to a low and nearly unusable value. This increases the distance to the fading zone, and reduces its width.

This, too, is from the research of RCA's George Brown of BL&E fame, as a result of his investigation and correction in 1935 of a serious amount of nighttime fading from a ~225 degree monopole used by 50 kW WCAU in Philadelphia.

Hi Wim

I'll admit I am having difficulty visualizing what you are doing with data tables and was about to suggest using a macro to generate the plot values until I saw your "no VB" comment.

When you say "data table", is that a pivot table? I have sheets with calcs based on pivot table outputs that are then used in further pivot tables. Looks horribly messy but it works. (Noting that the accuracy problems arent a problem for me due to what I am calculating for)

Cheers Bob W5/VK2YQA

Earlier I wrote:
I'm not considering that the ground wave signal _provides_ any of that low-angle DX coverage. It is the direct radiation existing in the radiation pattern of the monopole at low elevation angles that can do so.

... and as a postscript --

Even though in most cases amateurs don't care about the ground wave from a vertical monopole, a lesson can be taken from the broadcast community in that maximizing the radiation from a monopole at angles less than ten degrees will maximize the distance to the single-hop coverage radius (other things equal).

This can be done by using a vertical monopole greater than 1/4-wave in electrical height. A 5/8-wave vertical provides the highest gain in that elevation sector.

Getting back to Jerry's idea - yes, four linear dipoles can generate
nearly perfect omnidirectional c-pol. This is a design of Nils
Lindenblad many decades ago, and I've done some NEC-2 modeling of it.
The link below leads to a rendered view of that model.

http://i62.photobucket.com/albums/h85/rfry-100/LindenbladRendered.gif

This isn't true at least at VHF and UHF, where the ground reflection
mostly just reverses the polarization sense of the incident wave.
This have been demonstrated by the much-improved images seen on analog
TV receivers in city centers when using c-pol transmit and receive
antennas, because multipath reflections ("ghosts") tend to be
suppressed by the receiving antenna.

Here's a link to one example for VHF and UHF TV...

http://www.kathrein-scala.com/catalog/HDCA-5CP.pdf

Of course the Lindenblad, or even 1/2 of one could be used, also.
Using half a Lindenblad would make it true c-pol only in two
directions, but if you can aim it in the right direction that may be
OK.

I have for sale a brand new Telex Hy-Gain T-2X (Tailtwister) rotor. It comes complete in the original box and has never been used. The rotator has never been out of the box except when I took it out to test it. It is the older version without the plugs for the control cable. It has the original manual and accessory packet and it comes with approximately 50 feet of new rotor cable. It lists new for $799.95, and I'll take $475 plus shipping for it and the cable. See more specs at the Hy-Gain website at: http://www.hy-gain.com/Catergories.php?sec=8 Thanks, Charlie Hugg, K5MBX

Laport is authority enough for an instance for me. His data drawn
from field experience supports my model employing your reference which
responds to your complaint:
>>NEC far-field analysis this would seem impossible,
>>due to the greatly reduced fields in this sector
a statement that lacks quantifiables, and against which Laport's
example and my model only vary by 0.7 dB.

As I have asked in the past, what are your expectations for the
accuracy you expect? If it is tighter than 1dB (something exceedingly
difficult to accurately measure in the field for an absolute), then
that has been demonstrated. If it is tighter than that, your
expectations exceed the capacity of the equipment of that era that
established the FCC groundwave charts.

Richard
That is good information that has a trend to my way of thinking.

A heads up as to where this information comes from would be very
helpfull to
me in my on going experiments

These ratios of diameter to length does have a penalty in wavelengths
used
but hopefully in less reflector diameter which is not to be viewed as
a phase enabling point of view
If one viewed a helix as an array of loop radiators then phasing would
be important but then prevents
the formation of smaller volume radiation designs. For those who rely
solely on "off the cuff" thoughts
may well deride what I am doing but I have done my homework and am now
pursueing implematation
since experiments consist of more than the exercises of the brain
without the need of personal observations,
without which advances would be crippled and science laboratories
would become extinct
My thinking now leans toward solenoid style with a air bound core for
maximum flux density
within the core in "rifle shot" pattern. I have had a similar antenna
for the 80 metre band where the helix diameter
is just 4" which is quite directional even tho as low as 30 feet!.
Thus I am very much encouraged in

this new design which is light enough for me to carry and install
together with improvements added over my past effort
tho it will not have the tilting feature at least not in the near
future. I am anxious to add the tilting feature some time next year
in an effort to extend individual QSO time as propagation changes ,but
it is low on program requirements
Best regards
Art Unwin KB9MZ.....xg

If i had said it, you would have a field day accusing me of all kinds
of shit.

Since the late 60's i've been working with CB and have done all kinds
of experiments with antennas on a car. You name it, I had it.

As he pointed out, the big problem with CB is, you need way much more
space than a vehicle offers to truly get any usable gain from
cophasing.

Do you know the wavelength of 11 meters?
if 27 feet, the normal height of base antenna, is equal to 5/8 or 1/4
wave, then what is 8/8 or 100%? Well over 100 feet.

So to get the true proportion for proper cophasing, the road aint wide
enough and neither is the vehicle.

The only reason truckers run two antennas is because it looks cooler.

The effectiveness of cophasing in a truck is screwed by the factory
installed crap.

Far-field NEC analysis does not consider propagation loss for a
skywave and its reflection from the ionosphere.

Terman's Fig 55 does that, as well as to include earth curvature in
such loss figures.

If you can truly get within 1 dB of the FCC curves with your NEC model in the AM broadcast band then that's good enough for me. Probably not good enough for the FCC, though.

Richard
I would disagree with the above as it has it's roots in a loop array
yagi style
where phasing is of the essence. What Kraus did do is to destroy the
notion that
a radiator has to be straight to be effective which is borne out by
Gauss.
At the time he did his work (over 50 years ago) radar and other
advances pointed to the use of
higher frequencies and away from HF which then opened the advantages
of circular polarization
Thus his work to my knoweledge has not been extended to HF via known
observables, an avenue ideally
identified with hams with the experimental bent coupled with a
technical educatioin.
If others have already experimented in this particular area I would be
happy to hear of their experiences and actual
scalar obsevables.
The fact that my full scale experiments have exposed facts that are
contrary to that of 50 years ago
is what drives me on this task tho the labour tasking can sometimes be
exaspirating but non the less necessary
rather than relying solely on just personal thoughts, intuitions and
deductions,After all I am a qualified engineer
and certainly would not have got very far in life if I thought a

testing regimen is not a requirement any more

Maybe. I'm not an authority on self-employment and small biz.
However, I've been doing it for 25 years, so I must be doing something
right.

One of my "hobbies" was collecting business cards sitting on the
counter at the local retail electronics parts supplier. Every time
there was a layoff or downturn in the industry, a wide assortment of
business cards for newly minted consultants would appear. I would
grab a card, and scribble the date on the back. I would then wait to
see how long they would last. 6 months was the running average before
they found employment and/or decided consulting was not for them. A
few moved out of the area. I wasn't very organized or accurate, but
when the local economy sucked, there were perhaps 100 consultants.
When it was going full blast, perhaps 10.

A fairly small number survived over the years, and have built up a
customer base and revenue source sufficient to maintain their
lifestyle. Several have day jobs as well. One characteristic I noted
was the higher up in corporate America they went, the smaller the
likelihood of survival as a consultant. My guess is that this is
because of their addiction to the corporate support structure. For
example, I was horrified at the prospect of having to buy my own
stationary supplies, instead of simply stealing them from the company.

Another characteristic is that most consultants get their start by
obtaining work from their former employers. That included me. If you
burn your bridges when leaving a company, you will have problems.
Later, as your contacts move to other companies, your business base
will expand with them. If you have a mentor, do everything you can to
make them happy. I would say that without the business provided by a
very small number of industry contacts, I would have starved long ago.
I should also mention that I started my biz taking on small consulting
projects while still employed. I didn't need the money, but I was
bored and knew that I would evenutally need the experience and
contacts.

At one point, I had illusions of designing and producing antennas.
It's an ideal product. Few people understand how they work. Antennas
tend to be surround by hype and are often close to magic. Testing is
difficult and expensive. Product comparisons are non-existent.

Religion and bias toward specific styles and manufacturers seem to be the prime criteria for selection. The weirder it looks, the better it sells. Aesthetic concerns have provided a whole new market. There are already some rather dubious antenna products on the market. Etc. In all, it's a perfectly acceptable small market waiting to be exploited. Hopefully, my marketing and sales expertise will adequately compensate for my marginal antenna design abilities. I had plans to build the product line using the audiophile model, where garish industrial design and endless ambiguous buzzwords have done quite well. Due to health problems, I doubt that I'll do anything, so it's all yours.

Good luck.

And supporting my statement about the location of the fade zone not being a fixed 70 miles from a monopole, note this quote starting at the bottom of page 103 of that text applying to Laport's Fig 2.7 (your cited authority):

"For a 190 degree radiator, the fields are not shown because it is known immediately from the chart thus far computed that the signal will be severely noise-limited before arriving at the distance where fading is objectionable."

As Laport wrote his book Radio Antenna Engineering in 1952, he would have been working from the advantage of the research and discoveries of George Brown about this subject some 23 years earlier.

One of the most important paragraphs ever to have been posted to this NG ...

The logic and energy brought to bear is nothing short of astounding, and provokes a "RIGHT ON, THUMBS UP" out of me ... :-)

However, the part of success in selling snake oil, "In all, it's a perfectly acceptable small market waiting to be exploited", I'd have to see to believe ... the market seems saturated already!

Warm regards,
JS

Better yet, grab a hand full of plastic, glass, metal, wood, etc. and
toss it into a mud-puddle, come back in a few million years and see what
you can "dig up", what has "evolved" into being ...

While I cannot absolutely rule out molecules, atoms and other assorted
particles, materials and wavelengths of energies arranging themselves
into complex organisms, at least one of which has self-awareness--it
flies in the face of all forms of logic/maths/sciences I have ever had
contact with ... but true, ya' never know, ya' just never know.

Laport says much more than that about the fading wall. It took only
his one instance to correlate his chart to your chart and to my model
to give me pause to wonder what you are griping about when you
complain:
>>...NEC far-field analysis this would seem impossible,
>>due to the greatly reduced fields in this sector ....
a statement that lacks quantifiables. "Impossible" is
yellow-journalism fluff and the less than 1dB variations is within the
accumulation of field errors of the "possible" that went into
engineering reports. "Impossible" and "possible" are, to all intents
and purposes, describing the same thing.

What is it that is impossible? Or is this about seeming?

I have asked the trusties what the policy is regarding this before I
proceed.
I am in the rujst belt and there are many engineers that have and are
going to be laid off.
They will not be able to afford to stay abreast of things and thus
will be hurtin the coming depression.
Not good for the Countries future I would say
Art

What irks me is the video conference links that major universities have so
that their Russian counterparts can participate in the board meetings. Some
kind of open access thing. Them and Ron Burkle. What was this about
suppression?

Say it costs about $0.05/page for offset printing on glossy stock (no idea if that's right, but it's probably within a factor of 10). A 100 page journal is then $5 in raw production costs, per unit. (and we'll assuming binding, etc. is included)

But you have to add typography and editing and composition. I'd find it hard to believe that a complete journal could be set up in less than 100 work hours. So, about $10K.

If the circulation of the journal is 200 copies, then that's another $10K in repro costs. You're up to $10/issue, before you've distributed it, maintained the subscriber list, etc. These things all cost money (been there, provided the service, made a living from it, barely).

Check out what the "print to order" publishers charge. (e.g. Lulu.com) (100 page, paperback perfect bound is about $5.30, exclusive of shipping)

>

I think you'd have to go back quite a ways in time to get to $3/article. Grabbing a few things on my desk, a 2001 IEEE Proceedings article runs you $10. A paper in a 2004 Trans Antennas and Prop is $20. A 1982 Proceedings of IEEE paper runs $0.75. Jim Breakall's paper on HF propagation modeling over mountains in 1994 IEEE Trans A&P is $4.00

Of course, those are just the costs if you photocopy it yourself and submit the fee to the copyright clearance center.

And, a lot of times, the author of the paper will send you a copy, if you write and ask. (That's actually one of the fun parts about publishing.. Getting those post cards from obscure places in the world 10 years later: "Meine geehrte Kollege, bitte schicken Sie mir ....")

Granted if the author is dead or unreachable, that's a challenge.

>>
> Funny thing about "work for hire", the hiring entity is the one with
> any legal rights here in the US. But the NIH for some strange reason

One would have to look at the specific contracts/grant language, but I'll bet they require dissemination in something like PubMed these days. The days of the Principal Investigator keeping their data secret for decades while they dribble out a paper a year, are dying, if not dead, at least for publicly funded work.

On NASA missions, there's typically a clause that requires dissemination of the raw data from an instrument within 6 months, and you're required to have budgeted for that dissemination in your proposal.

The IEEE does not publish work for hire
> generally, but charges for submissions.

Of course the IEEE publishes work for hire. If you work for Boeing, write a paper, and get it published, Boeing owns the copyright (as work for hire), and executes a license to IEEE to use it. And they don't always charge for submissions. My very first published paper (wasn't with IEEE, as it happens) had the page fees waived, because I was in high school at the time.

My transistor radio antenna of 50 years ago was smaller than that and
could do better at lower frequencies: Triple the wavelength, 4 times
smaller, and at one tenth the height. That is a 120 fold advantage
over your design. It cost $12, and the antenna came with it for free!

Self-arranging and self replication are actually easy enough to do that the old definition of life that depends on that have been discarded for much tighter definitions, Otherwise we would already be able to claim that we created life.

As an example, lipids, or phospholipids, are a common substance (read oils) that have the tendency to form into small bilayer spheres that isolate the interior from the exterior world. Then what is needed is for the right compounds to get trapped inside that sphere, and maybe something interesting will happen.

A immune system analog:

http://www.sandia.gov/media/NewsRel/NR2002/nanoarch.htm

Point is, these things are not some impossible to happen, "just so" scheme. As time goes on, it looks more and more like on a planet capable of sustaining life, life will happen.

Now if someone wanted to claim that some entity made that planet that could support life, then these things happened - that is a different story.

> What is it that is impossible? Or is this about seeming?

---

1. A far-field NEC analysis of the elevation radiation pattern of a
monopole over real earth shows little to no relative field below 10
degrees elevation. No doubt that is true of your NEC model under
discussion here, is it not?

2. Terman's Fig 55, and the experience and field measurements of AM
broadcast stations for many decades shows that there is _considerable_
radiation launched in this sector. In fact for monopoles of 5/8 wave
and less the radiated field is maximum in the horizontal plane.

How would you characterize the discrepancy existing between items 1
and 2 above?

You still didn't give any useful information. No surpise since you have none. For an average of the cb band running 1/4 wave the antennas should be spaced 54 inches apart. Use a commercially produced cophase harness if you can find it. Make sure you match the SWR and you will out do any other mobile off the front or rear.

Hello to Bob and the other contributors

I used the table function that enters row or column data into a
formula and plot the result under the row or right to the column. I
use the 2 variable version that results in a square with 400 cells. I
add them with the sum function.

The reason for mentioning "VB not preferred" is because of when I have
to divert to programming, I prefer to abandon Excel (for this
application) and use another environment.

Following this thread and advise from other people, I will abandon
Excel for this Fresnel calculation.

Regarding stability issues, some people also advised me to use the
Unix/Linux program instead of the windows port. So I still have to
do some investigation, as I do not have a machine with Linux on it.

Best regards and thanks for the info,

Wim

Acording to my mentor (now retired), the secret to success for a small business is to find a narrow corner of the market, so narrow that it won't attract the attention of the big guys, and do everything you can to own it. Small companies just don't have the resources of the big guys. The trick is to avoid them, not lock horns with the big guys.. Therefore, I don't see anyone going into the land mobile, TV, tower, GPS, cellular, or car antenna business. These certainly are saturated, although you might be able to compete on a cost basis. Where small companies have succeeded are in the niche markets, such as Stepper IR, various weird CB antenna contrivances, and wi-fi antennas. If you've got connections in Homeland Security, consider military and paramilitary antenna system.

As for snake oil, I don't consider giving the customer what they want to be snake oil. If the market demands garrish, weird looking, strange, camouflaged, and/or colorful antennas, it's not snake oil. Several vendors have demonstrated that weird looking sells well. If that's what the customer wants, I don't see a problem.

It's also possible to produce deluxe versions of common antennas. For example, I suspect a gold plated antenna, with rare earth doping to improve conductivity, and ceramic insulators made from clay found in Area 51, to be sellable. It's not that far from what I read in the audiophile catalogs, with their $500 power cords, wooden amplifier boxes, glass turntables, and acoustic pretzel speaker enclosures. You might not sell too many of these deluxe versions, but you'll make lots of money on each one.
<http://www.audioadvisor.com>
<http://www.audioadvisor.com/prodinfo.asp?number=CRGRPC>

Remember, the surest sign of success is pollution. Since the market for antenna products are not yet totally polluted, I don't consider the market to be anywhere near saturated or successful.

Of course, the manufacturer would have to live with themselves. I would go as far as the goofy pink antenna I mentioned above. I don't think I would have the lack of integrity to make the bogus claims made for stuff like the Audiophile industry does. They have a distinct Carney/Rube thing going on with their customers.

I got it!

My urine contains special compounds because of my consumption of asparagus, chocolate and beer. This cause my urine to have special properties that cause magnetic particles to increase their flux concentration, giving increased power output, more brilliant lows and Highs, and making for much less listening fatigue.

I will sell bottles of the miracle liquid for 1000 dollars per liter. However, as everyone knows, ther eis nothing like freshness for the important compounds, so for 25 thousand dollars plus air and food expensies, I will come to visit and pee on your speakers......

>degrees elevation. No doubt that is true of your NEC model under
>discussion here, is it not?

I see that this question bears on my previous correspondence where you
have failed to attend to that relevance. In fact, my model's 1ï¿½
response is only 1.6dB below the peak response at 8ï¿½ (both of which
are below 10ï¿½). That peak response is roughly half a dB below a
perfect ground response at 0ï¿½.

I will again repeat two questions that seem to plague you to the point
of silence in their regard:

1.
What is the relevance of your side topic? Please answer it within
that side thread where I raise this question.

2.
>>>...NEC far-field analysis this would seem impossible,
>>>due to the greatly reduced fields in this sector ....
your statement lacks quantifiables. "Impossible" is
yellow-journalism fluff and the less than 1dB variations I have
reported are within the accumulation of field errors of the "possible"
that went into engineering reports. "Impossible" and "possible" are,
to all intents and purposes, describing the same thing.

What is it that is impossible? Or is this about seeming?

Hi Wim,

Unix/Linux is all fine and well, but if the package is OS sensitive,
then that package is suspect in its own right. The OS has (should
have) nothing to do with the libraries that perform the computations.

Your aversion to VB is well founded in shared libraries (I presume,
however, your aversion is for coding, but the visceral response is
true to form).

Going back 25 years ago when I was designing FFTs. I wholly abandoned
MS whose expensive compiler and math libraries (upwards to $600) were
abysmal in comparison to the $50 TurboPascal product.

Then your NEC analysis is not a _FAR-FIELD_ NEC analysis, as repeatedly I have referenced in my posts, and even as is shown in your quote of the same point, above.

I suggest you carefully read and consider what I write as many times as is necessary in order to avoid such gaffes.

The rest of your post of the date/time quoted above I will dismiss, as I have already responded to it.

<<> hi thanks very much for responding

I should have mentioned that all the antennas are mounted on heavy
ga metal support masts around 10ft and bolted to a brick wall
of the elevator room

i am up 14 stories building wouldn't let me run any wires to
ground on the outside of the building from the roof wish i could

so currently it's just my ice protectors inside my apt on 4th fl
'grounded' to the elec

is't really to much i have access to living in an apt, i'l like
to be able to chip the concreate away inside the elevator room to
get at a beam and clamp onto that but they wouldn't allow that
nor penatrating the room to feed the wire out

there is a electrical box up there i suppose i might be able to
run a small wire from it to the masts not sure if code will
allow using elec conduit in an elevator room as a 'ground ' in
this fashion i suspect not and the inspector is up there
regularly and not sure how much lightning protection that would
afford maybe bleed al little so a smaller hit

i appreciate your sharing the ideas
thanks

So, how do we parse your reply? I see the assertion from you
>>>no relative field below 10 degrees elevation.
I see from me
>> my model's 1ï¿½ response is only 1.6dB below
>> the peak response at 8ï¿½ (both of which are below 10ï¿½).
>>That peak response is roughly half a dB below a
>> perfect ground response at 0ï¿½.

To the greater part of the community in this group, the difference
between
>>>no relative field below 10 degrees elevation.
and roughly half a dB below perfect at 8ï¿½ elevation (which qualifies
as below 10ï¿½ elevation) would leave us to believe you equate
no relative field = a field at 0.6dB below perfect
Unless, of course, you care to ammend this with quantifiables of your
own.

This portends you cannot answer for your assertion:
>>>...NEC far-field analysis this would seem impossible,
>>>due to the greatly reduced fields in this sector ....
your statement (now statements) lacks quantifiables. "Impossible" is
yellow-journalism fluff and the less than 1dB variations I have
reported are within the accumulation of field errors of the "possible"
that went into engineering reports. "Impossible" and "possible" are,
to all intents and purposes, describing the same thing.

What is it that is impossible? Or is this about seeming?

Sorry, but a similar product has already been invented and been on the
market for about 5 years:
<http://j-walk.com/other/wifispray/>

The ladyfriend would probably buy the pink antennas. She just bought
a pink bicycle. In disgust, I bought her pink garden tools and a
stuffed pink pig. That might also explain why I'm spending the
evening posting useless usenet drivel, instead of engaging in
debauchery. Anyway, pink is the "in" color, so I guess it's ok:
<http://images.google.com/images?q=pink+camouflage>
<http://images.google.com/images?q=pink+products>

At one time I was labelled an "effet commie liberal pinko swine" (or
something like that), but that was long ago.

Octave (the Matlab clone) is available for almost all platforms, and is
quite easy to learn to use. For things like manipulating matrices and
vectors, it's pretty slick. The real Matlab has better graphics
packages (in terms of integration with the package, etc.), but from a
straight out computation standpoint, Octave works just as well.

[snip]

Hmmmm....

Roy, I don't believe that is a "complete" description of circular polarization either.

My understanding is that circular polarization is what we call the polarization of electromagnetic radiation when the electric field vector E rotates with an angular velocity rather than oscillating back and forth in a single (linear) direction.

Roy, your description of circular polarization above seems to imply that the angular velocity of the E vector of a circularly polarized wave is always "synchronized" with the signal frequency since you stated that it rotates at one revolution per cycle, or one radian per radian per second.

This of course is the (normal?) situation if the antenna is say a helix firing along its axis or say crossed dipoles fed with a 90 degree phase shift, but... to be more complete, we should note that...

Circular polarization does not have to be "synchronous"!

Consider...

What would you call the polarization type of the radiation emitted by the following radiator?

An ordinary linear dipole fed with RF from a feedline through two slip rings arranged such that a mechanical drive is able to rotate the dipole at some arbitrary mechanical angular velocity completely unsynchronized with the RF carrier.

For example, say it's a 5m dipole driven with 30MHz carrier signal and mechanically rotated at 1000 revolutions per minute.

Such an arrangement would result in circularly polarized radiation with the E vector having angular velocity of 1000 revolutions per minute and a carrier frequency of 30MHz which definitely is not one revolution per cycle.

Thoughts, comments?

No John they are like souls, looking for some body to talk to,
Looking for some body to argue with,Looking for somebody to fraternise
with.
Leave them alone as they are so happy at this time making friendly
fools of each other
like the chant of two natives bouncing around a wood fire banging two
sticks together.
While they are slapping each other like guys like kb9..... can write
in peace knowing that for
the moment they are safe. Personaly I am happy that they have found
each other thus
leaving others alone for cordial conversations and debate without the
concern of seeing
a foot suddenly appear from the next cubical. Soon the whistle will
blow when they both

Sure can. Collins Radio used mechanical resonators in an HF radio ISB
diversity 2240 baud modems. Then they used a switched capacitor meta
resonator. Then they used DDS synchronous comparison. And of course
there are various narrow band filter methods. And of course whatever
internal method the 8870 DTMF decoder uses. Who knows what methods
can be implemented in fast UC or small DSP or even an FPGA, except it
will not be a mechanical resonator. I suppose a mathematical model of
a mechanical resonator though.

Hi Pete

Your idea of rotating a linearly polarized 30 MHz dipole at 1000 RPM does not relate to the term "Elyptical Polarization" which is often called Circular Polarization. The Wikipedia information is fairly complete as it defines CP..

That is not going to cut it. You Must have protection "on the roof"
to comply with code. You need lightning arrestors on each feed line
on the roof.

>
>is't really to much i have access to living in an apt, i'l like

Not a small wire, you want just as big at the ground wire to the
electrical box, a small wire will not protect.

Art wrote:
"I would disagree with the above as it has its roots in a large yagi style where phasing is of the essence."

Kraus says on page 268 of the 3rd edition of "Antennas":
"The natural adjustment of phase velocity so that the fields from each turn add nearly in phase in the axial direction accounts for the persistence of the axial mode of radiation over a nearly 2 to 1 range in frequency."

In Kraus` 1950 version of "Antennas" on page 178 he writes:
"A first-order transmission mode on the helix, designated T1, becomes permissible when the helix circumference lambda in free space is of the order of 1 wavelength."

I don`t argue with Terman or Kraus.

Best regards, Richard Harrison, KB5WZI

> Thanks Top!

I think that Top's calculations (and recommendations) are a bit off?

CB has an 11-meter wavelength. There are just over 39 inches in a
meter. Hence, the wavelength is around 430 inches.

A 54-inch separation is only .12 wavelength. From the chart in the
ARRL Antenna Book, it looks as if you'll get less than .5 dB of
directional gain, compared with a single radiator of the same type and
size. That's less than one tenth (!) of a nominal S-unit. You'd be
very hard put to be able to detect this small of a difference in
practice - it'll be less than the amount of signal variation you'll
encounter due to reflections from nearby objects.

In terms of getting yourself a directional-gain benefit, I think a
co-phased two-radiator broadside array with a 54-inch separation is
essentially useless on CB frequencies. There just isn't enough gain
to matter.

Now, as somebody else suggested, using such an array might get you a
more consistent near-omnidirectional pattern than a single radiator
would deliver, if your antennas are mounted less than optimally (e.g.
on your sideview mirror post). Using two co-phase antennas might be
worthwhile for this reason, even if you don't get a significant amount
of directional gain.

I suspect you'd get more bang for your buck by simply mounting a
single antenna in a better location (e.g. roof mount) and paying
attention to making the antenna's grounding to the chassis/groundplane
as direct and solid as possible.

>reading before you try to correct anything.

The directionality of a broadside array (with the two radiators fed exactly in phase) depends very strongly on the separation between the two antennas. For separations of 1/4 wavelength or less, there's very little directionality - the pattern is very close to omnidirectional.

Every dual-antenna truck setup I've seen has been a side-by-side mounting (e.g. one on the left mirror and one on the right), and the harness feeds them both in-phase. I've been assuming that this was what was being meant by "co-phase".

If so, I stand by my statement that two CB antennas, fed in phase through a co-phase harness (i.e. no phase difference between the two), and separated by only 54 inches, produces a nearly-omnidirectional signal. The two antennas need to be further apart, before the pattern becomes significantly directional.

Take a look at the NEC plots at http://www.cosjwt.com/index.php?a=20 to see... the 4.5-foot separation model produces a pattern which is almost circular. There is little gain towards the front and back, and very little loss off to the sides. These plots seem to jibe well with other references I've read (Terman, Kraus, and the graphs in the ARRL Antenna Book).

The other alternative is an end-fire array, with the antennas fed signals of opposite phase - with these then there can be significant directionality even with close spacing of the antennas. In a truck-antenna system, this would require placing the antennas one in front of the other, separating them by several feet, and inverting the phase of the signal sent to one of the two antennas (perhaps by having the feed coax to one antenna be 1/2-wavelength longer than the other). You could get several dB of gain this way... but the close spacing will cause the antenna feedpoint impedance to drop a lot, and some form of matching network will certainly be required to keep the radio happy and develop maximum power from the transmitter.

The two bottom plots on the site I mentioned above, show the effect of feeding the antennas with signals of different phase. In these examples, the pattern is being skewed off to one side - the difference in feedline length is converting the antenna from a broadside array to

an end-fire array. With the right amount of phase shift, you end up
with a cardioid pattern, with a broad lobe in one direction and a very
deep null in the other.

I'm a "single antenna" guy myself.

I think, in a truck, at least, that "big radio" is synonymous with "big
wristwatch". :-)

We can't mount the antennae high or center, because the 13', 6" height of
the truck is where the low bridges start.

Also, most tractors have this horrific system that intergrates AM/FM with
the CB coax.

A CB stick on the left mirror and an AM/FM on the right, and a splitter in
the coax, so I always run my own coax seperately.

And I have a cellular antenna on one side, any way, for dual plane signal
boost, and it has to be 8" (I think) away from other sticks.

But hhhhhere's a question for the braintrust:

I'm after a (mobile) VHF radio that's common to northern (i.e., the Yukon,
and Northwest Territories) Canadian truckers- who don't monitor CB bands.

(info:) http://forums.qrz.com/showthread.php?t=171741

I'm sure, as a sine wave challenged layman, that I can't use the same
antenna and coax as my CB?

That certainly doesn't fit the classical definition of circular polarization. Circular and linear polarizations are special cases of elliptical polarization, which all fields actually have, and which is universally defined in terms of polarization change over each period. Whatever you want to call the field your mechanical arrangement is producing, it's not circular polarization in the sense universally used in the literature.

The polarization reversal on reflection occurs only when the wave is
normal to a large (in terms of wavelength) flat surface. If it reflects
at a glancing angle, the sum of the direct and reflected rays end up
being nearly linear, or at least elliptical, depending on the reflection
angle and reflection coefficient. Glancing reflections from ground are
just about impossible to avoid at HF, but the also occur at VHF and above.

I suggest you stick with the amateur market, which pretty much fits your description. There are other antenna customers, though, who depend intensely on antenna performance for the operation and performance of their products and missions. All my consulting clients, and a large number of my professional software customers, are in this category. They can't afford careless or substandard design, and simply won't tolerate it.

Damn, you overthink things. The subject is PL, as generally used in
2-way mobile and hand-held radios and base stations. There are a few
variations, as a handful of tones have been added to the original group.

The receiver looks for a tone in the audio of an incoming signal. If
that tone is heard, that part of the squelch system unmutes the audio.

I have no idea how you got from that to Collins HF Modems, but I'm sure
it was a lovely trip for someone.

Almost got it right but a little off.

The higher the "meter" the frequency gets lower.
11 meters is roughly 27mhz.
10 meters is roughly 28mhz.
2 meters is 144 mhz.

A "wave" is based on the physical length between nodes of the
frequency.

In reality, one wavelength at 27mhz is about 36 feet long.
A standard 102inch whip is a 1/4 wave antenna.

Just for you mister know it all top,
you might want to gander at this site.

http://www.cosjwt.com/index.php?a=20

It blows your 54" theory right straight to hell and then some.

As you'll see by the charts, there is virtually no difference between
1 and 2 antennas mounted on a truck.

Ya gots to understand with whom you are trying to communicate.
"Top" is the master know it all who has absolutely no background in
electronics. He just drives a truck and thinks that gives him the
knowledge. You've heard of "Billy Big Rigger"? You just met the dude.
Top just goes along with what other truckers have said over the years.

I have the actual working experience to back me up with.
The only thing Top knows about CB is how to yack on it.

No dumbshit.
As I have tried to explain to you once before, DO NOT buy one of those radios. If you get caught with it in the USA alone, and are transmitting on it, no license? Bye bye. Pay the $10,000 fine lose the radio.

Every trucking company in Canada that uses them has a Canadian license to operate them with. They are not like CB's. They are commercial business radios.

I trust maybe now you'll listen to one of the radio experts for a change.

Would one of you in the radio groups who knows Canadian radios please explain this to the jerk?
He thinks that because he's a trucker, he can have any damn radio he wants in his truck.

"Alligator effect" normally refers to higher transmit power (not higher
antenna gain) -- big mouth, small ears.

>If you don't need to
>pickup everything then why bother? It just makes it harder for your WiFi
>router to cut through all the noise of distant stations it doesn't
>communicate with. ...

It actually usually makes sense, since higher gain means narrower
receive pattern, which better rejects off-axis interference.
Interference in exactly the same path is possible but unlikely.

This confirms my earlier observation that you had no support for one
rather meek word game from you:
>>>...NEC far-field analysis this would seem impossible,
>>>due to the greatly reduced fields in this sector ....
your statement (now statements) lacks quantifiables. "Impossible" is
yellow-journalism fluff and the less than 1dB variations I have
reported are within the accumulation of field errors of the "possible"
that went into engineering reports. "Impossible" and "possible" are,
to all intents and purposes, describing the same thing.

What is it that is impossible? Or is this about seeming?

If you cannot support your own statements with quantifiables, I can
see why you shy from further pale elaboration.

None of this disproves the idea that the universe is created along with the laws of physics and the bio-chemical engines that conform to the will of God. Let's face it, science doesn't disprove creation theory at all. It simply tries to explain and make use of what we are provided with. Doesn't mean we shouldn't give thanks.

The Bible explanation of creation isn't more specific than what was appropriate for a developing intellect. Any one with any true intellect will be in awe with the realization that all of the laws of Physics, the extremely refined and complex Bio-Chemical engines that contribute to life in all its forms, and the extreme odds against a planet with the narrow margin of environmental conditions, all would fit the definition of the greatest miracle known. To be known by the only species enabled to know it.

Whereas we struggle to understand where we are and what we are capable of in the here and now (and fall miserably short) The Bible actually dares to and does predict the future and stands as the most insightful understanding of our past, our nature, and hope for the future.

I can certainly understand how people could have a beef with "religion". After all, the Bible even warns us of superstitious people, God haters, hypocrites. Jesus himself warns in his parables that many would be among the righteous planted by the enemy to discourage, usurp and mislead. Who doesn't know of those in a group that gossip and tear down others. It's like a boat on the ocean and some are chopping up the main mast for firewood because they just want to be comfortable, while some are chopping a hole in the hull because they are curious of what is on the other side and have no discipline or forethought. He never said it would be easy.

>antenna and coax as my CB?

In principle, you could combine the CB output (27 MHz) with the VHF
radio output (up above the 2-meter band) using a diplexer, and feed
the result down a single coax.

At the antenna end, you'd have a couple of choices. You can use
another diplexer to split out the HF and VHF signals, and feed them to
two separate antennas. Or, you might be able to find a single CB-type
antenna which is also capable of matching up well enough on these VHF
frequencies to work tolerably well.

The chances are very poor that a randomly-selected CB antenna would
give you a tolerable SWR on the 160-or-so-MHz VHF band... and if it
did, there's no telling what its vertical radiation pattern would look
like. An antenna intended for these two bands would probably have to
be custom designed - I can think of a couple of possible ways to do
it. Such a dualband antenna would almost certainly be a compromise
antenna on both bands - it wouldn't work as well as separate antennas
designed for best operation on a single band each.

Commercial HF/VHF diplexers run somewhere around $80, last time I
looked. You'd probably find it less expensive in the end to just run
a second coax and put up a second (VHF-only) whip antenna.

Exactly, a matter of public record here that Richard has seen several
times previously, and just forgot.

Here's Richard's esteemed military career (and how he was caught lying
about it): http://bolo_bullis.tripod.com/

What's amazing is that Richard and I were just discussing what a total,
absolute and complete asshole he makes himself look like every time he tries
to make himself look tough or smart at anyone's expense.

Of course he can't hear a word of that, and immediately starts this.

Richard, who is also a career pedophile and damn proud of it, has had, and
will always have, the same problem, and that's that he just can't keep his
festering gob shut.

What amazes me is that he's skunked a dozen usenet groups over the years,
is internationally know as a scumbag, but still sees the world through his
own rose colored glasses, like we might have forgotten his previous and
extensive bombast and flummery.

Funny, or sad?

I am.

They said the radios were available, the <private> frequencies, not the
radios, are licensed, and the freqs I'm interested are available to the
public.

And the license, if you want one, is easy and cheap.

Were your mother and father related -before- the wedding?

Inquiring minds want to know.

Because you have an uncanny resemblence to the Deliverance banjo boy.

> Would one of you in the radio groups who knows Canadian radios please
> explain this to the jerk?
> He thinks that because he's a trucker, he can have any damn radio he

Jesus, are you stupid.

Try reading the thread that I cited, that flatly proves you wrong.

And as I already stated, and you apparently forgot, the radio would be for emergencies only, and that I would have no reason to use it in the states.

Your memory is just shot, fuckhead, have you ever met a guy named John Francis?

Or been to Australia?

I find it amazing that you'd be afraid of an FCC fine, that I have a one-in-ten-million chance of -ever- receiving, while you publically brag about being in possession of 45,000 child pornography pictures.

Amazing. Simply amazing.

Thanks!

That's the kind of helpful and intelligent response I was looking for.

The radio would be for emergency communications anyway, to trucks in
the -immediate- vicinity.

The 4 "LADD" frequencies are used by the scale houses up there, as well.

Since this thread is going to groups who do not know me, I will try to
clairify the lies here.

>
> Here's Richard's esteemed military career (and how he was caught lying
>about it): http://bolo_bullis.tripod.com/

First, that is an exact copy of my dd214 acquired under the FOIA.
It states I served. Unlike the lies that promulgate from it that says
I did not.
2nd, why is the word before "discharge" blacked out? That was not done
by the US goverment. It was done to make it look more damning.
I never claimed to be anything I was not. I said I never got beyond
boot camp and my highest rank was E1. The dd214 confirms that.
I said I had enlisted for the ASA but never got involved with it.
While others claimed I had claimed to be super secret spy or in
special forces. Most of those lies were all created by "Just Taylor".

>
> What's amazing is that Richard and I were just discussing what a total,

>festering gob shut.

Pedophile being defined here as a person who others claim is a
pedophile because the damning word sticks to more feeble brains than
any other word. No one has ever proven, in 10 years, that I am, have
been, or currently am, a true pedophile. It's nothing more than ill
words on a screen.

Trust me. he has no clues as to what you just said.

This fool wants to run a vhf radio in Canada just to talk to Canadian
truckers. He thinks those radios can be bought and used just like a
CB.

As I have operated radios on 47mhz, held a 2nd class fcc license, I think I know a lot more than he does.

I'd offer a "metoo" for some advice you got from another poster... do
NOT operate unlicensed. Don't even install a radio for which you
don't have whatever license is required by the law in the areas in
which you will be driving.

Planning to use the "Officer, it's only for emergency use" response,
when challenged, could be a very expensive tactic. You might find
out, the hard way, that the local regulatory body takes a "possession
is considered proof of intent to use" approach... even if you don't
get hit with criminal charges or a civil forfeiture order, you could
find that your radios are considered de facto "contraband" and are
subject to being seized without warning.

Here in the US, unlicensed operation could get you hit with equipment
confiscation and a fine of many thousands of dollars.

If you want to operate VHF, you should either get a proper license
(e.g. for business-band frequencies) or stick to radios which have no
legal requirement for a license. For example, here in the U.S., the
MURS (multi-use radio service) is a collection of a few VHF
frequencies (formerly licensed-business-band) which have been
reassigned, and which can be used without a license as long as the
radio you use is properly certificated for this purpose.

I don't know if Canada has a MURS-equivalent, or if any of the
truckers up there use it. Check the regulations before you buy.

Hello Richard, John and Jim,

First, Thanks for the info. I downloaded TP55 via the link. Good thing that Embarcadero (sounds 100% Español) makes available older versions of popular software.

One of the options I had in mind, was to use an older version of Delphi. I prefer this above VB. Structured design isn’t strange to me, so Pascal, is still attractive for me (though it is not as popular as years ago). My lecturer for high level programming was Mr. L. Ammeraal.

I know Turbo Pascal was very popular. Later, many people I know used also the Delphi product (both free time and professional SW development). After that some people switched to C++ builder.

Best regards,

Wim

Are you always this whimsical? I would point you to Acts chapter 2 but you obviously haven't read any of the Bible or have no reading comprehension. If you were taught that someone's opinion is more important than your own investigation, you are misled. Perhaps you haven't been in a book store lately. If you are skeptical of the translation, bravo! You understand that men can fail. Get a parallel Bible and see how closely the meaning follows. You will find instances of references of what was to come, and what has very nearly completed.

Thanks, but don't put too much stock in the idiot.

I don't chat on the radio, regardless of how he tries to project his own activities on others, and from what I can discern so far, no license is required.

I notice Richard the expert hasn't provided any such information, either.

Possibly you're not aware of this, but unlicensed 10 meter radios with in-line amps are quite common in our trucks, and openly sold (although one major truckstop chain was, I believe, fined after several warnings) everywhere.

I'll be happy to get a Canadian license if I can, but, I don't need or intend to use the licensed business frequencies.

So, if as I understand, -that's- what I need a license for, I have no need for one.

From the cite: "The Canadian equivalent of the FCC has a site in which it post Northwind Trucking as 165.840 MHZ.. Now in Canada they do not partition the VHF High band into commercial 151-162 and Government 162-174 like we do.. they are all over the place. Also They provide unlicensed LADD channels which are used alot by trucks Ladd 1 -154.1 Ladd 2 -158.94 Ladd 3- 154.325 and Ladd 4 173.370.. Again they are all over the place with stuff up there. Most of the action on Inuvik is on VHF. Nothing appears to be on 30-50 MHZ and the Hospital and Airport are using UHF."

"They provide unlicensed LADD channels which are used alot by trucks"

"They provide unlicensed LADD channels which are used alot by trucks"

"They provide unlicensed LADD channels which are used alot by trucks"

"They provide unlicensed LADD channels which are used alot by trucks"

Where I drive is not where you live.

http://picasaweb.google.com/Popeye8762/20071202Yellowknife#5143243959490865794

That radio may mean the difference between freezing to death or not, or,
literally, being eaten alive.

"Officer, it's only for emergency use" is certainly preferable to that,
and, grossly unlikely anyway.

I've been through a score of vehicle inspections, with an illegal kicker
in -plain sight-, and nobody gives a damn.

They're a whole lot more concerned if we have brakes, and are sober.

Contrary to Stupid Richard's rantings, I've never seen an FCC roadblock in
35 years of driving.

> Planning to use the "Officer, it's only for emergency use" response,

But whether you're right or wrong, Richard, you can't state anything without a demeaning attack on others, usually embarrassingly incorrect, like you just did to Top.

It's because of your angst and poor self-esteem, probably because of the inbreeding.

And not man enough to correct yourself, from your flagrantly idiotic rant about Top being "billy bigrigger" (when he doesn't drive truck), a term you use frequently, that describes, well, you and Roger, more than anyone else here.

If Top was wrong, you could have -easily- made your point without being abrasive, as others did, yet you attacked.

Which is why -you're- always attacked.

Because you DESERVE it, Richard.

You actively -earn- the animosity of others, because you CAN'T KEEP YOUR FUCKING MOUTH SHUT.

>> Of course he can't hear a word of that, and immediately starts this.
>>
>> Richard, who is also a career pedophile and damn proud of it, has had,
>> and
>>will always have, the same problem, and that's that he just can't keep his
>>festering gob shut.
>
> Pedophile being defined here

No, Richard.

No.

Not "pedophile being defined" however it's convenient to you.

Pedophile -has- a definition, and I've posted it many times, with your grossly inapropriate posting history.

It's a matter of -permanent- record, Richard, and you can't spin puppy shit into butterscotch pudding.

>as a person who others claim is a
> pedophile because the damning word sticks to more feeble brains than
> any other word. No one has ever proven, in 10 years, that I am, have
> been, or currently am, a true pedophile. It's nothing more than ill
> words on a screen.

>
>>
>> What amazes me is that he's skunked a dozen usenet groups over the
>> years,
>>is internationally know as a scumbag, but still sees the world through his
>>own rose colored glasses, like we might have forgotten his previous and
>>extensive bombast and flummery.
>
> While shitheads like you keep wanting to let the world know about the
> past anyway they can. No proof, just a lot of hot air.

I just state the facts, -with- the proof.

You're the one with the revolving definitions and X-files DD214.

You could clear that discharge up -anytime-, and choose to make excuses
instead.

We -know- why, Richard.

>> Funny, or sad?
>
> Sad boy you are

If I was any happier, I'd have to be -two- people.

>and you wore a uniform?

Yeah, for an entire enlistment, imagine that.

I know that's a foriegn concept to you.

>God help us all.

Worry about yourself, dude.

Not a fuckin clue, Richard, and not ashamed to admit it.

What ever it is, I can learn it, teach it to myself.

I'm not afraid to ask questions, like the one that set you off on this rant, and I'm not afraid to ask for help.

It's -easy- when you're a man.

> This fool wants to run a vhf radio in Canada just to talk to Canadian
> truckers.

That's all in your mind, a baseless lie you repeat with no evidence.

I've stated, clearly and concisely, what the radio is for.

It's your projection of your own actions that leaves you apoplectic.

I'm sure when you're on the radio that you irritate working drivers for miles, till they won't respond to you anymore, and then you key the mike on pathetic country music.

Since -you- do that, -everybody- must...

>He thinks those radios can be bought and used just like a
> CB.

Well, sort of, yes.

My CB is illegal too... ;-)

And no one gives a -damn-.

My 78 Suburban has a ten meter radio and a boat radio in it, neither with a license, for twenty years now.

> As I have operated radios on 47mhz, held a 2nd class fcc license, I
> think I know a lot more than he does.

No one cares.

Still waiting for you, 10 posts later, to provide some actual information instead of the screeching and wailing.

Is that a threat?
Let me know when you have proved that rocks came out of nothing,
spontaneously. Then prove life sprang up out of rocks, then prove you
sprang up out of that. You have a long way to go in your religion. In any
case, good reasoning, common sense and good education Left the country long
ago. The dating issue is the only real point of contention, but the Bible
doesn't really specify a date for creation or if it refers to the whole
universe or to our solar system or out world. The specific details of
creation, as in how it was accomplished just aren't there. It's easy for
you to say billions because no one you know was there. My point is:
Science can't prove so you shouldn't slam the book shut just yet.

When you meet your maker, you will have more than your ego to worry about.

So, you're a legend in your own mind. Your reactivity by the way indicates you have belligerent tendencies and probably a fascist. The multiple posting may very well mean that you take quite a while to calm down to sanity when you flip out. Work on that or everyone will know where your buttons are and you will be too easily manipulated. But then, you might not have a job unless you were easily manipulated. Another paradox.

Teachers, God bless them, have the position where they assemble knowledge that has been passed to them and must unquestioningly accept that knowledge or take considerable time out to investigate that knowledge themselves. It is a major paradox. There once was an old saying, but it is too unkind. I would like to rephrase it; Those who do, do and those who teach, don't have time to do.

Cecil
The antenna will be capable of use on ALL frequency so I will be able
to observe the ups and downs of the reflectors applicability when I
get it up.
7 inches of snow with two more clippers on the way has put a crimp in
my immediate plans
My thinking is that as the antenna is end fed the need for extra large
size reflecter goes out the windown
as the reflector may perform as a flux guide similar to a long
solenoid. This is new ground so I do not
want to nickel and dime it to death until I have more experience under
my belt. Present dish
education is heavily weighted to phase methods used in planar designs
or alternatively solely on VHF,
the later being slanted designs via pitch and other factors that do
not apply in my case. since my
design evolves around equilibrium . I would also point out that some
of Kraus's work is being thrashed
with respect to gain and may well extend to use of deductions instead
of observables which was heavily used
in empirical gains with respect to pitch angles. Bottom line at the
moment is that the antenna for top band
be light and small enough for me to handle on the towerand on the
ground without the need for me use my prop pitch rotor,
which by itself is a handfull or to call for additional help. If I
can't handle it alone then it defeats my original object with respect
to
small antennas without the normal compromises with respect to
electrical wavelength.
That ofcourse does not rule out diode action in the short run with
respect to poultry fence mesh as a reflector.
Regards
Art

Dave let's agree to our own experiences.

Now to Richard

You forgot who you are talking to again. Nothing unusual for
you to get things wrong. I don't drive a truck unless you are
talking about a pickup. As far as electronics backround I was
in communications in the Army. I spent a good bit of time in
the field in sitiuations where I had no backup so I had to
know enough to make things work when they broke. I don't mean
simple backpack radios either. Then there was the year I spent
teaching radio wave propagation. Another year teaching
programming small and meduim size telephone switches. In 2005
(well after I had retired) I spent the year assembling boards
to build MRI machines. If you think I have no electronics
knowledge then as usual you brain is no bigger than you little
toe.

The ARRL Antenna Book says that with 1/8WL spacing,
one can achieve 4.1 dB gain with a high F/B ratio.

Recently got back into radio after 15 year absence..... Have a
question for you antenna gurus. I want to put up a 135 foot doublet.
Question is: Does it need to be supported in the middle? The layout of
my property has no support for the middle of the antenna.

Actually, the two end supports which tend to make the
antenna horizontal are more useful than a single
center support for an inv-V. Short answer is "no", you
don't need a center support.

Cite, please? For which antenna configuration and phasing?

I believe that the high (4.1 dB) figure you are quoting is for an end-fire array, with the two antennas being fed 180 degrees out of phase. Good gain, but somewhat tricky to feed and match due to the low feedpoint impedance and the potential for high losses.

In a truck-antenna situation this would require placing the antennas in a front/back arrangement, not side-to-side. I'm told that this is rarely feasible.

The usual two-antenna truck arrangement I've seen is with antennas side-to-side (one on each rear-view mirror), fed in phase. This is a broadside array, not an end-fire array.

From all I can see (ARRL Antenna Book, Kraus, Terman), a two-radiator in-phase broadside array doesn't start to achieve significant gain (and pattern non-circularity) until you have at least 3/8 wavelength of separation between the radiators. A 1/4-wave separation yields only around 1.1 dB of gain, which (by my calculations) works out to about a 15% increase in useful range in the preferred direction.

My book's at home, but my recollection is that you can't get 4.1 dB of gain out of a two-radiator in-phase broadside array until you have more than 1/2 wavelength of distance between the radiators.

It would seem to me, there are but two ways to couple to the ether,
either capacitively or inductively, if such is even possible (there
could be "something else", who knows?)

At a certain ratio of capacitance to inductance, in the design of an
antenna, that "magical/mystical value" of 477 ohms would be reached.

However, you emphasize the inductive coupling ... I see other antennas
emphasizing e and h fields and all sorts of stuff in between.

In all this mumbo-jumbo something may, indeed, exist ... to date, "I
just don't get it" ...

Unfortunatly for you he is correct about cophased antennas less than 1/4
lambda. What the antennas do is to merge the distorted wave patterns
of each antenna into one pattern. Each antenna displays a slightly
distorted pattern that favors the side of your truck that it is mounted
on. The two patterns equal one centered pattern.

I don't emphasize inductive coupling, at least not with what I am
messing with now!
Inductive coupling infers planar antennas acting solely on
intercoupling of elements
while at the same time ignoring the edict of equilibrium that goes
with all laws of science
such that the effects of the "weak force" are ignored. With inter
coupling of elements
you only get approximations as the last element of any array
reradiates half of that
which it receives. Thus the array always needs another element
regardles of the number used
to obtain maximum radiation. In the case of array in equilibrium you
always reach finality
with respect to radiation. All very simple.
On the other hand this 477 ohms figure certainly is mystical to me,
what is the point you
are trying to make? Is it possible that the figure you are using is
bigger than you intended
by being larger than life itself

>
> In all this mumbo-jumbo something may, indeed, exist ... to date, "I
> just don't get it" .

I will take a wild guess here and assume there is some connection to
the
aether which is eternally on your mind. Well John for equilibrium the
aether is contained
within an arbitrary border. That means that all forces add up to zero,
a simple concept of Newton
which also means that the contents are not nothing or a vacuum what
ever that is in celestial terms otherwise the border collapses.
You must also realize that what is within the border must be in a
state of spin as well as being in equilibrium
where spin requires the present of matter. So now you have a basis on
which one can define the Aether
which is something other than nothing or a vacuum. Knowing that
particles flow thu this that is surrounded
by an arbitrary border one could possibly state that for every
addition of a transient particle another particle must
leave and since particles atract or repel that which is in circulation
in spin form must in fact be cluster form of particles.
So John let your mind have a smidgeon of freedom accepting what is
known and put things together the best way you can
so that you have a datum line to build on or change as knoweledge
increases which allows the addition of logic by the removal
of past theoretical assemblies.
All the above is material that you can use in your determination if I
am of sane mind or not. But first you must set your mind free
accepting only that which you can personally derive from first
principles as something that can be built upon.

Brrrrr it is geting cold
Goodnight
Art

It depends on how much sag you can tolerate. Less sag and/or more feedline
& antenna weight = greater tensioning.

KD3Y,
I have a 220 foot dipole with a substantial amount of dacron rope
to the end supports.

I use a 40lb box of Cat Litter on one end to terminate the rope
which runs through a pulley. Although I use lightweight feeder
spreaders, the center does dip some which might affect the
resonant frequency of the antenna, I use a tuner and the
antenna "works" on all bands.

If you don't use a setup like this, it is difficult to get enough
tension and prevent the tree supports from breaking the
antenna. The antenna, made of #10 copperweld, has
stayed up through a number of NE winters.

Actually 135 degree phasing and a cardioid pattern.
180 degree phasing results in a figure-8 pattern with
3.3 dB gain.

Was out of town during the holidays and didn't realize
that the earlier statement was limited to a side-by-side
configuration.

> In a truck-antenna situation this would require placing the antennas

Yes, but what better place than the top of a metal
trailer? Years ago, I helped a CB friend in AZ install
one on his motor home with about 5 foot spacing if I
remember correctly. Measured front to side ratio was
huge.

That would be some pretty short antennas on top of a semi trailer.

I had an arrangement like that on a school bus turned RV many years
ago. It worked great until I found a low underpass in Waycross Ga.

To sort of sum things up, how your antenna is supported, center/ends, isn't going to make a lot of difference. Of course, building the thing strong enough to support it's own weight is a 'biggy'. Making it 'fit' the area you have to work with is also a 'biggy'. Then it's just a matter of 'making do' with what you got, sort of. Probably won't be the absolute bestest in the world, but so what, it'll work.
- 'Doc

(when you figure out where to place those 150 foot towers, and make the whole mess rotatable, THEN you can worry about it... right?)

Thanks everyone. One thing I have in my garage is empty litter cans
that I can fill with sand and use!!
Hope to get antenna up in next couple of weeks. Right now I am running
a approx 40 foot doublet in my
garage roof, anxious to get the larger outside antenna up.

Oh, I WOULD propose that 477 ohms is "real"; indeed, it as real as gravity. That is the ONLY reason you would find it in antenna calculations and mentioned in books ... however, you are quite correct, it seems it only serves as a "placeholder" and as a "magical number"--its' only purpose, to make equations and assumptions work which would otherwise not ... what that 477 ohms "really is", is the crux of an important omission/guess/fudge-factor/etc.

Art, I believe you sane enough, you simply "poke at matters" which are taboo ... and, I am loathe to be more specific. You either see the discontinuities which prevent "the picture from being complete", or you do not. If I felt I could go even further out on a limb, I would. For now there are only questions and a search through others thoughts ...

Guys.. this is nowhere near a "two 1/4 monopoles over a uniform ground"
that you're seeing in the handbook.

The antennas are 30cm or so from a big metal box (the tractor), and
possibly in close proximity to a even bigger metal box (the trailer).

Before one starts going on about whether you get any gain from two antennas 1/8 wave apart or whatever, look at whether it has any practical benefit in terms of, for instance, filling in nulls.

Modeling (either computational or on a range) would answer

So would practical experience. I suspect that there's enough "real" benefit from the dual whip configuration that it persists.

5161. confusion about path loss calculation for zigbee

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-04 18:15:36 UTC
From: Ginu <osheikh81@gmail.com>
Message-ID: <886fe89d-1769-4ce4-8d37-d167bb81dab7@q9g2000yqc.googlegroups.com>
Source record: 19334

Hello,

I've been trying to wrap my head about this problem for days and can't seem to figure it out.

Zigbee technology allows you to transmit at 250 kbps. I'm comparing the required power to transmit at that rate to the required minimum power based on the path loss equations to reach the minimum receiver sensitivity of the 802.15.4 physical layer for Zigbee of roughly -94 dBm. Simple enough right?

To analyze the required power to transmit at 250 kbps for Zigbee, I've just re-arranged the Shannon capacity formula of Rate = w * log_2 (1 + (Pt * G)/(w*N + I)). Here, w is the bandwidth, Pt is the transmit power, Pt * G is the received signal power, N is the white Gaussian noise and I is the sum of interference powers.

For Zigbee, these values are as follows:
w = 5 MHz
N (in dB) = 10*log10(k) + 10*log10(T) where k is boltzmann's constant of 1.23E-23 and T is the temperature in Kelvin of 300 degrees. In Watts, N is approximately 3.6900e-021.

I've assumed no interference at this stage, so I = 0. Simple enough so far right?

So to calculate the required transmit power to reach a rate of 250 kbps, I've just re-arranged this equation to yield:
Pt = [2^(250 kbps/w) - 1]*(w * N + I)/G and plugging in the above values gives me a reasonable transmit power of 1.6 uW.

The reason I haven't talked about G yet is that I'm addressing it here. G is the channel quality (path loss) and is defined as follows:

G(freq,D) = GrdBi+ GtdBi- 20*log10(4*pi*freq*d0/c) - 10*pathLossExponent*log10(D/d0) (in dB)

I'm using unity gains so GrdBi = GtdBi = 0 dBi. Other parameters are:
freq = 2.4 GHz
d0 = 1m as the reference distance
c = 3.0 x 10^8
pathLossExponent = 2, and
D = 500 metres

Hence, G (in Watts) * Pt is the received signal power. G(2.4E9, 500) is the path loss transmitting at 2.4 GHz a distance of 500m away. G (2.4E9, 500) = -94.0254 dB

Now the first thing that I mentioned was the receiver sensitivity for Zigbee of -94 dBm, Analyzing G (in dB). The required transmit power considering this path loss is easily calculated as:

-94 dBm = P_required + G(2.4E9, 500)

P_required is then easily calculated as -94 dBm - G(2.4E9, 500) = 0.0254 dBm. This translates to a transmit power of 1 mW. This required power is LARGER than the maximum permissible power to transmit at 250 kbps, which is the maximum data rate for Zigbee. So how does this make sense?

However, 1mW happens to be the maximum transmit power of Zigbee of roughly 0 dBm, so there may be a range problem here.

Testing other distances, say 300m, we get a maximum transmit power Pt = 5.9181e-007 = 0.59 uW to transmit at 250 kbps, but a P_required = -4.41 dBm = 3.6211e-004, which is > our maximum transmit power Pt.

So again, we run into the same problem at 300m. It just doesn't make sense to me. Can anybody shed some light on this? I hope my math is clear. Thanks in advance.

Just a bit of clarification. The node needs to transmit above
P_required for successful reception at the receiver above its minimum
receiver sensitivity, but this P_required is greater than the power
that correlates to a data rate of 250 kbps. To me this doesn't make
sense. I thought I should add in that conclusion. Thanks.

Cecil:

LOL!

I was slow on the uptake, sorry old man ... :-(

I know that is a terrible sin here, one I make too frequently ... you got me! I punched [1 x "fs"] into the calculator, got the ~377 and immediately recognized my error ... just gettin' old and slow here ...

It was wise of you to make a point of it ... thanks!

Regards,
JS

John,
my first point was the 477 error but you didn't catch on.No problem
Regarding taboo. When the gloves are taken off then every thing
goes !.
The first person to fire does not make the rules for what then ensues.
When a animal kicks you in the crotch then there is a good chance it

has rabies
and you do what you have to do,. Ofcourse you can run away but then
that
would be very painful and lasts a life time. Let it drop
My very best regards
Art Unwin KB9MZ.......xg

That potential (and quite possibly real) benefit has already been
mentioned a couple of times in this thread.

>So would practical experience. I suspect that there's enough "real"
>benefit from the dual whip configuration that it persists.

I strongly suspect that you're right, and I think I've been trying to
make that very point. The benefit to a typical two-antenna truck
setup isn't that it provides a lot of gain (and thus a
non-omnidirectional pattern), because in fact it doesn't (the spacing
is too small). Rather, the practical pattern is going to be closer to
a true omnidirectional pattern than can be achieved by a single
side-mounted antenna alone. The final pattern may actually have
less gain in a few directions, but may have shallower nulls and thus
a more consistent overall coverage.

It's one of those weird situations, in which the reason for the
benefit that can be perceived is actually just the *opposite* of what
one may believe at first!

I must admit a bit of scepticism in re Cecil's suggestion to use a
90-degree-phase-shifted endfire array feed... at least, for most car
and trucking applications. Granted, it'd give quite a bit of gain in
the forward direction... but at the expense of a deep null in the
rearward. It'd be great for speaking with the guy a few miles in
front of you... but you'd lose the ability to talk well with the guy a
few miles in back of you. If every vehicle used this sort of antenna
pattern, overall coverage would probably be worse (4 dB of gain in the
forward direction wouldn't compensate for a 10 or 20 dB null in the
rear direction of the next vehicle).

The theory is that for mobile CB, one wants radiated energy
distributed up and down the highway, not to the sides.

You and Cecil, both, have my location in error ... I DON'T live in the Gay Bay! (i.e., San Francisco) :-)

Personally, I am attempting to get my representatives to sponsor a bill to give every documented gay person $100,000 to move to Texas!!!! <evil grin>

You would also lose interference from the rear. Simply
arrange a switched phase-shifting feedline that can aim
the beam forward or backward. It's like a Yagi mounted
on a motorhome.

Environment's no excuse for bad behavior, but it is often the case. Maybe you haven't seen any miracles in yours. They can be found even amongst great turmoil and evil. Try to get out of your comfort zone and travel some, even spend some time in other cultures. Jails of Mexico, Beverly Hills, anywhere. It can be a better teacher than the classroom. I can pray that you're eyes be opened to what you can't see.

What on Earth is going on here? So you have a conflict?
What do you both want of each other so this can be put aside
if you so wish?
The subject was that many technical people are getting laid off.
This removes them from access to public university white papers.
After a year or so they will be encouraged to look for a alternative
career
They then find that that University white papers are not open source
to facilitate recomended change
Universities widen the Rust Belt towards both coasts. Universities
decline in services without public funds
Universities react and recruit teachers from India to prevent furthur
spread of the Rust Belt but efforts to late.
America becomes the latest Empire to bite the dust as a Mexican
becomes P=resident and encourages change
over from corn to hemp and all are happy overnight. The audacity of
hope fades away.

The climate in Texas is not very good for gays. Texas
is the only state that still has the legal right to
secede from the Union. Don't be surprised if it happens
under Obama's "rule". One of his transition staff actually
asserted that he would be "READY TO *RULE* FROM DAY ONE".

Don't think that you will be alone. Although, "they" attempt to paint my state as a bunch of gay-pinko-commies, some of us don't think so ...

However, given the "last eight" and the party which got us here, I am willing to see what happens first (Bush NEVER lifted a finger to repair the criminal actions of Clinton--NAFTA is only one example.) And, IMHO, printing 850 billion dollars and giving it away to those using practices which got us here in the first place is NO ANSWER ... I'd say the fox already runs the hen-house.

Keep your finger on the trigger, but don't fire until you see the whites of their eyes ... :-)

Texans are too chicken to secede from anything, but it's a nice thought.
If Texas were to secede, the rest of us could say, (stealing from Dr.
Martin Luther King) "Free! Free, at last!"

However?

As for:
> I hope my math is clear.
If your conclusions for these case tests depart from rational
expectations; then you have one of two possibilites:

1. Your math may be clear, but wholly invalid (transcription error of
complex formulas into ascii text is a bummer);

b. Your math may be clear or murky, and otherwise entirely correct,
but you did it wrong.

iii. You suffer from transcription AND "plug-n-chug" errors;

four. Zigbee technology doesn't work.

If this is a classroom problem, you need to resolve it yourself. If
this is an engineering problem, what did the Zigbee help-line offer?
There's probably a simple nomograph posted at their website or in
their application notes.

So at 5AM I may not be too sharp...

The formula you used doesnt seem to allow for the required demod s/n. QAM64 for example (from memory) is around 30dB so this has to be "added" to the path loss. Differing mod/demod/FEC have differing margin requirmeents. Somewhere in there too you have to stipulate the bit loss rate "allowed".

In the past I use to calculate the noise floor at b/w, apply RX noise figure and then add the margin.

When I last did this I upset my employer by saying that their marketing hype was flawed. They had specified a lowest usable sensitivity that after applying the required demod s/n was below the calculated noise floor for that b/w. We were in fact consistently getting RX sensitivty issues during the manufacturing phase for this reason... Marketing had created a spec that wasnt possible!

Also, I dont know about 802.15 but I do know that 802.11 has variable data rates (ie bandwidth) that can be advertised something like "54Mbps and -87dBm sensitivity". The numbers dont actually go together. At 54Mbps you might get -77dBm and you have to use 11Mbps to get -87dBm!

I'll admit I havent studied your maths in detail....

The above probably not a lot of use to you... Sorry!

Cheers Bob VK2YQA

Phew! Stop to catch your breath Art. 8^)

Actually, I wondered what this thread was all about.

So I'll bite.

Much of what is out there is free for all.

But the source of the money for research is often from companies who
are using the research to enhance their companies position in the
marketplace.

Now we can discuss how much of a public university is actually public, and whether or not it should all be public or not, but the background has shifted.

Once upon a time, industry funded an amount of their assets toward research. As time went on, some folks decided that that research money was wasted, and was better spent giving back to the shareholders. That was a smart move - if you couldn't see past the end of your nose.

So after it was seen that wrecking your R and D department was a great way to become a technological backwater, they started looking for a less expensive way to get research done. The answer was the universities. So here we are. We can argue about whether or not it should be all open source or not, but from industries perspective, not having the research open to all makes sense.

Needless to say, a one paragraph dissertation of the situation is necessarily truncated as all hell....

Not to say one way is better than any other, although personally, I kind of liked the older paradigm of company based R and D. But the new method sends money to the universities.

Excellent point Mike.

When I returned to bring my degree up, the department received quite a chunk of money from the military, and a military contractor, for research into weapons targeting.

A sane mind does need to be in control and differentiate between TRUE "public knowledge" and non-public knowledge ...

And, a public college should refrain from getting into the position of competition with private industry (or, even influencing competition in public industry)--EVEN if the money and perks are tempting. We used to have men of such high standards, morals and ethics involved that there was little if any controversy ... :-(

I just built one of these using thin wall 1 1/4" aluminum tubing and
bare 20ga copper wire for inside. It was a tri band
for 50, 144 & 440 mhz, section = 1/4 and 3 x 1/2 wave then top 1/4
section cut for 146mhz. SWR is higher than I
like but it receives and signal reports are so much better than my
factory 5/8 antenna I will now try to lower the swr.
I used short pieces of PVC to couple the tubing, its freestanding and
15' tall, very light weight, I used old swmming pool cleaner
telescopic pole for the elements.

Mike
My point is that IF the work of Universities is to be published it
should be open source
instead of giving it to a private entity. I see no point in preventing
oversite by the public at large
from seeing how their taxes are being spent. The fruits of our taxes
should not be channelled off
to prevent private institutions from going bankrupt. Private
companies can always, and do, have their own Rand D
if they want totally privacy for commercial reasons. PARTIAL funding
does not give them the right to the same
privacy. As the pool of engineers get smaller so does the disemination
of scientific information,.
Is that what America really want for the future?

but many universities ARE private entities. And if private funds are used for research, or funds from industry sponsors are used, then there should be no doubt that the funder's should decide what gets published and what they keep private.

> I see no point in preventing
>oversite by the public at large
>from seeing how their taxes are being spent.

have you actually gone to a public university and asked for access to their library where such things are normally archived? personally i don't think i need to pay to have everything done at a public university published for the world. that would be a bigger expense than the research is actually worth in many cases.

>As the pool of engineers get smaller so does the disemination
>of scientific information,.

Engineers are NOT scientists. Engineers design things that perform specific functions, they may solve practical problems, but they are NOT the ones doing most of the basic research type of work. At my last job they wanted to change my job title from 'Engineer' to 'Scientist', this was a place that DID perform research that was funded by industry, most of which was kept private for use by the funders. I refused the job title change because I preferred to do the practical stuff and make products for the customers that did something useful instead of the research and experimentation and writing reports.

I wonder how long that sentiment would last if we demanded full
disclosure and retention of patent rights from those on the dole who
claim they are inventors?

* * * * T I L T !!!! * * * *

The question becomes: Are you willing to pay back your social
security to the taxpayers who support you?

Knowing how that answer will be evaded, avoided, denied, dismissed
(each or all with manufactured outrage suited to this Soap Opera), no,
you won't. As Perot used to say, "That dog don't hunt!"

As such, the status quo will be maintained and inventors on the dole
will keep their dignity and professors will keep their research.
Equilibrium! ;-)

At 3 times the standard depth of skin depth the density is 5 percent
of that on the surface, below which only copper losses with respect to
a time varying current. So what exactly forces a time varying current
to take an alternate route of travel from the center of a conductor
when the resistance is so low compared to other routes that could be
taken.?
Note : center resistance is lower than that on the surface because
skin depth (opposing eddy currents) cannot form.

I think that question is probably best answered with a question(s) ...

What is a thin element?; What is a thick element? What is the surface area of the element(s) in question?; what are the power densities involved?; Does the surface quality of the element cause these measurements to vary?; In all cases ever recorded, is it ALWAYS the level you gave, i.e., no anomalies?

I have always thought 1/4 copper tubing with a tenalized SS welding wire of heavy gage though its center was superior at high power, a lot get by with much thinner elements. On 10m and lower, I would, generally, use heavy wall copper pipe of 1/2", or so ... on wifi antennas, I use 1/8 heavy wall brass hobby tubing--I suspect no advantage over thin wall.

I would love access to facilities to investigate this, that lacking, I would love data I could trust ... what do you find so interesting that rf might be forced deeper into the surface of elements? I assume from all my readings and studies that rf prefers the surface--the higher the freq(s) the more the phenomenon is noted/enforced.

Regards,
JS

Well John the impedance gets lower as the percent of the wavelength
goes down
Exercising limits when the radiation surface is zero then so is the
radiation
The point I am stating is that a fractional wavelength is less that a
wavelength
and copper losses thru the center is less than an ohm so where is
there a lesser
impedance route fot the current to travel to become a closed circuit
without radiating?
I am just making the point again that antenna knoweledge on this

newsgroup is very sparce
Most do not accept I sq R jn all cases,and most will not accept the existence of a Faraday cage!
RF does prefer to exist on the surface if and only if contra forces cannot be over come.
But then "engineers are not scientists" according to one poster so perusal of white papers is not necessary
as the truth is unimportant. So the single question again.....
What is the lowest resistance part from the top of a fractional wavelength antenna to obtain a closed circuit?
Simple and to the point and no word games as the application of true true science is indicated to those thus qualified
Art

5201. Circular polarization... does it have to be synchronous??

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-06 01:17:45 UTC
From: "Peter O. Brackett" <none@no-such-domain.nul>
Message-ID: <dq-dnZXd6Y0gT6TUnZ2dnUVZ_rjinZ2d@earthlink.com>
Source record: 19475

Group:

Warning... this could be mind blowing!

Conventionally electromagnetic wave 'polarization' refers to the relative physical spatial orientation of the electric field vector (E) of an electromagnetic wave.

It is commonly understood that polarization of electromagnetic waves may be either linear or circular.

Linear Polarization (LP):

Of course waves that are linearly polarized may have any arbitrary orientation angle (theta) with respect to a reference frame such as the earth's surface. For example most common linear amateur antennas produce and/or respond to waves of linear polarization, and these antennas produce either either horizonally or vertically polarized waves depending upon the orientation of the (linear) antenna with respect to the earth's surface (ground).

As examples; a 1/2 wave length dipole for 10 meters hung at 30 feet between two trees of equal height produces a largely horizonally polarized wave and, a 2 meter 1/4 wave dipole mounted in the center of the roof of an automobile produces a largely vertically polarized wave.

Of course as electromagnetic waves are propagated throughout an environment are never purely orientated and usually contain an ensemble of many orientations, because the waves are reflected from the ground, trees, buildings, mountains, bridges, moving vehicles, and sometimes propogated through moving and anisotropic media such as the ionosphere, etc... and so the multiple reflection surfaces at various angles to the earth's surface and/or refractions and Faraday rotations will conspire to "mix up" the original orientation of the E vector of a purely linear transmitted wave and usually produces a quite mixed polarization at distance from an emitting antenna.

Malus' Law {I = Io [cos(theta)]^^2} describes the response of a linearly polarized receiving antenna to waves arriving at a polarization angle theta relative to the receiving antenna's preferred orientation. i.e a horizontally polarized antenna will produce maximum response to horizontally polarized waves and a minimum response (zero) to a vertically polarized wave and vice versa.

Of course in practice, because of the multipath reflections and refractions the 'cross response' is never exactly zero or maximum as predicted by Malus Law.

Just the same it is preferable to have the orientation of a receiving antenna 'aligned' with that of a particular transmitting antenna. In the HF region it is difficult for hams to "rotate" the orientation of their receiving antennas to maximize signal pickup based upon polarization, and so most hams are forced to take whatever response their relatively fixed antennas produce to the relatively unknown orientation of received waves.

In military or commercial installations, where money and space may not be an issue, either electronically or mechanically derived spatial antenna polarization diversity can be utilized to maximize received signal strength based upon arriving polarization. Polarization diversity receivers...

Circular Polarization (CP):

Circular polarization describes the condition when an electromagnetic wave is spinning or rotating with around its direction of transmission. That is the electric vector (E) of a circularly polarized electromagnetic wave is rotating with an angular velocity as the wave travels through space. This is in contrast to the E vector of a linearly polarized wave which merely oscillates in one linear direction.

Just as with linear polarization (horizontal and vertical) there are two different distinctly possible orientations for circularily polarized waves, these are known as Right Hand Circular Polarization (RHCP) and Left Hand Circular Polarization (LHCP). There are actually two well known conventions used to label R and L CP depending upon the community of interest, namely physics/optics and electrical/electronics. Usually electronics folks refer the direction of rotation to the rotation of the E vector around the direction of travel from a transmitting antenna, whilst the optical physicists refer the rotation of E around the direction of travel towards a receiving lens. It's the same as the definition of up and down, it's all in the eye of the beholder. Regardless there are two orientations for CP

Apparently circular polarization is less commonly known and understood than linear (horizontal/vertical) polarization especially among hams.

There exist RHCP antennas and there are LHCP antennas. Perhaps one of the easiest forms of CP antennas for hams to understand are the axial mode helix antennas first discovered/studied by the great radio astronomer/ham John Kraus W8JK. Axial mode helix antennas may be "wound" with either a right hand thread or a left hand thread.

Again Malus Law applies, in an easily applied modified form and so... RHCP receiving antennas respond to RHCP waves and LHCP receiving antennas respond to LHCP waves. A purely RHCP antenna will produce zero response to an LHCP wave, etc...

An interesting effect happens upon reflection of CP waves. An RHCP wave reflected from a perfectly reflecting surface returns (is echoed) as a LHCP wave!

CP propagation is often used in Satellite communications where a satellite may use both RHCP and LHCP transmitting antennas on the same frequency for

communicating independently with two different ground stations using R and L CP antennas on the same frequency. CP frequency diversity doubles channel capacity!

Yet another common form of CP antenna uses crossed linear antennas fed with a 90 degree (Pi/2) phase difference excitation.

As far as I know all currently known CP antennas such as axial mode helixes and crossed 90 degree linear arrays produce CP waves where the angular velocity of rotation is one revolution per cycle of the RF carrier, or in other words one radian of circular rotation for each radian of frequency transmitted. In other words most well known CP antennas produce ONLY synchronous CP, where the angular velocity of rotation of the E vector is synchronized exactly with the frequency of the wave being transmitted.

I believe that the well known and understood situation of purely synchronous CP is NOT necessesarily the only form of CP.

Warning... The following may be an invention!

Consider the case of a linear antenna, say a dipole, fed from a feed line over rotating slip rings, such that the antenna can be rotated while it is transmitting.

Now transmit on that dipole antenna whilst mechanically spinning it clockwise [RHCP?] (with a mechanical motor of some kind).

The dipole antenna is linear and thuse emits linear polariztion, except it is mechanically spinning, and so the E vector emanating from the antenna will be rotating with respect to its direction of travel.

In this case the angular velocity of the motor that spins the linear antenna need not be synchronous with the frequency being radiated.

For example we could mechanically spin the antenna at 330 rpm while transmitting a carrier of 1 GHz.

This would most certainly produce circular polarization. For is not the E vector spinning at 330 revs!

In fact the astute newsreader may note that we need not use a motor to rotate the antenna. In fact, I can propose several ways of "electronically" rotating the linear antenna at any arbitrary angular velocity, not necessarily synchronous with the transmitted frequency and so produce a so-called non-synchronous CP at any desired rate of rotation.

Clearly, according to Malus Law, the maximum response to the non-synchronous CP received waves from this 'rotating' antenna contraption would be from a similarily rotating receiving antenna!

Question?

What would be the response of an axial mode helix antenna or say crossed 90 degree fed dipoles or any other "synchronous" CP antenna to such a non-synchronous wave produces by a rotating antenna?

Would the response of a syncrhronous axial mode helix be less than that of a sympathetically rotating receiving antenna?

What?

Thoughts, comments?

Good grief. wilkipedia that you refered to is absolutelly correct
I am looking for somebody well vested in RF. If you can point to
an error in the given mathematics text
then you can regain my respect.
Pretty hard to do without a modern college education in physics or
electrical engineering
Next self perceived expert come forward.
Art

I expected someone to pop-in with an ultra-simplistic explanation, and poof!; Claim the problem explained ...

I myself pay enough attention that, I can see the point you make. Indeed, anyone with even half-a-brain, interested in rf and having worked with antennas in a hands-on reality, i.e., build rather than buy, would have come across this enigma.

Real world example:

I have watched amateurs pump 1+KW into, what I consider, incredibly thin elements/conductors (my math skills indicate current carrying capacity of the wire is being vastly exceeded, at points/nodes.) And, it has struck me that I don't see this element vaporize at a current node! Indeed, I don't even see a pronounced sag/heating/softening of such elements ...

The simple/short explanation makes all our "antenna prophetic/predicting" formulas and equations work ... the long explanation is a bit more complex, me thinks ...

Peter O. Brackett wrote:
> . . .
> It is commonly understood that polarization of electromagnetic waves may
> be either linear or circular.

Then some education is in order. Electromagnetic waves are elliptically polarized. The two extreme special cases of this are linear and circular (with axial ratio of zero -- or infinite depending on your choice of definition -- and one respectively). There are an infinite number of other possible elliptical polarizations with different axial ratios.

> Linear Polarization (LP):

> the earth's surface (ground).

Of course linear polarization can have any orientation, not just vertical or horizontal. And even those terms lose meaning when away from the Earth. However, it's often convenient to mathematically separate waves into two superposed components of horizontal and vertical polarization.

> As examples; a 1/2 wave length dipole for 10 meters hung at 30 feet
> between two trees of equal height produces a largely horizonally
> polarized wave and, a 2 meter 1/4 wave dipole mounted in the center of
> the roof of an automobile produces a largely vertically polarized wave.

The polarization of the dipole signal will be purely horizontal only directly broadside. The signal off the ends are purely vertically polarized, and in other directions neither horizontal nor vertical.

> transmitted wave and usually produces a quite mixed polarization at
> distance from an emitting antenna.

By "mixed" polarization, I assume you mean a single polarization which
is neither horizontal nor vertical and can be described as a "mixture"
of a purely horizontal and a purely vertical wave.

> Malus' Law {I = Io [cos(theta)]^^2} describes the response of a linearly

It's also difficult to get the polarizations of the antennas exactly right.

There's no advantage at HF of having the antenna orientations the same
if the path is via the ionosphere.

Interesting. Can you work an example for us? I'm curious as to what you
use for theta in the "law's" equation.

> An interesting effect happens upon reflection of CP waves. An RHCP wave
> reflected from a perfectly reflecting surface returns (is echoed) as a
> LHCP wave!

Only if it strikes the surface directly head-on. Otherwise you get an
elliptically polarized wave. The axial ratio depends on the angle of
incidence and, if the reflector isn't perfectly conducting, on the
impedance of the surface.

> CP propagation is often used in Satellite communications where a

I think you mean that polarization (not frequency) diversity doubles
channel capacity.

That is, in fact, the definition of circular or elliptical polarization.

> I believe that the well known and understood situation of purely
> synchronous CP is NOT necessesarily the only form of CP.

It's the only one which fits the definition. If you choose to rotate the
polarization at some other rate, you should call it something else.

>
> This would most certainly produce circular polarization. For is not the
> E vector spinning at 330 revs!

Sorry, it doesn't. An unavoidable side effect of the synchronicity
change is that the amplitude of the E field still changes at a 1 GHz

rate, going through a complete cycle from max to zero to max to zero to max each nanosecond. A circularly polarized wave doesn't change amplitude with time. A non-circular elliptical wave changes amplitude but not fully to zero each cycle.

Circularly polarized waves have many characteristics and particular relationships to linearly polarized waves. The waves you're producing don't have some of these characteristics, like the constant amplitude. Your method doesn't produce circularly polarized waves even though the polarization does indeed change with time.

Because a circularly polarized antenna responds equally well to all orientations of linear polarization, the normal helix wouldn't be aware of the polarization rotation -- unless the polarization rotation was fast enough to be nearly synchronous.

> Would the response of a syncrhronous axial mode helix be less than that

John., there are one or two who can provide the correct answer.
One is an old timer on this group from years ago who I believe is well
versed in RF
and has made a couple of postings lately. Funny thing is that when an
addition was made to electrical laws by Heaviside
and Maxwell it was just an addition to bring the laws into
equilibrium! Ofcourse, those units encompassed a formula well suited
for a displacement current.
However the idea of waves versus particles exist to this very day even
when Foucualt discovered the presence of a separate current that fit
the initial addition by Maxwell and searched for so long by Einstein
before abandoning classical physics and plunged it to relativism for
the answer on the understanding that the "weak force" was part and

parcel of radiation and a subset of an existing force. He died and there is nobody left to apply authoritity to his thoughts. I can just imagine what woild have happened if Einstein extended the static law by making it a dynamic field which by its equivalent to Maxwell would have placed particles and equilibrium firmly into radiation. Just imagine Einstein having possesion of a computer program of today with optimizer that excluded planar designs in the face of an array in equilibrium. I know of nobody familiar with the present antenna programs who can explain the addition of the "'Weak force" that creats arrays in equilibrium without a hint of parallelism or planar construction. Have all the antenna computer programmers also died or do they have a quiet distrust of their work with respect to Maxwell ?
Now we have the relevalation that Neutrinos DO actually have mass obtained frtom the Sun which puts another nail in the coffin with respect to waves.
Yes, American Universities deserve their failing grade.(Read Asimov thoughts on present science teaching)

Actually, no, general programmers fill the planet, competition for work is high ... well, perhaps better in china, india, etc. :-(

However, programmers "don't much" appreciate programs which play horseshoes. We like EXACT answers, exact measurements and routines which CONSISTENTLY return EXACT figures, dimensions, etc. ... in true math there is but one answer, artists see things in gray, programmers in black and white. When a program says, "Well, you start here, with this measurement, and prune, or lengthen", or, "You start with this capacitance (or inductance) and then adjust as necessary", I feel ill.

Example:

IF Pi X 3 = circumference ever fails (I expect it to be just as accurate for a 1 inch circle as a 1 million mile one), or returns a "figure to begin experimenting from", I will see it as only a guess also ... and requiring an artist to deduce.

Antenna design parameters are a nightmare ... indeed, since that which is not a science is an art--antenna design looks very much an art to me ... or, at least mixed fields of discipline are required.

Now, one Art should recognize another art ... <grin>

And, I am done with this whole discussion, someday we will have accurate tools to work with ... end of story.

Regards,
JS

The Wikipedia treatment is not incorrect, but it may create a false impression that the skin effect is limited to some particular type or cross-section of conductor.

There is a more general derivation by Davidson that has far fewer restrictions about the assumed geometry. There is a scanned copy at: http://www.ifwtech.co.uk/g3sek/misc/skin.htm

Davidson shows much more clearly that the existence of a skin effect does not depend on any particular shape or size of conductor, or any particular type of electrical circuit. If RF current is flowing in a conductor - regardless of the reason - then the skin effect will be present.

That is a very powerful conclusion. Because we know the skin effect will be present, it helps us to trace the RF current pathways on complex shapes such as coaxial cables and shielded loops.

the same as for a linearly polarized wave. since the rotation frequency is
much lower than the carrier frequency (unless you are considering elf
transmissions) during any time period consisting of several cycles of the
carrier it would appear stationary to the antenna.

>
> Would the response of a syncrhronous axial mode helix be less than that of
> a sympathetically rotating receiving antenna?
>

it wouldn't matter. now if there were two linearly polarized antennas
rotating such that their polarizations stayed in sync that would at least
reduce the fading caused by one rotating and the other being stationary.
but only if the path between them didn't produce any rotation or
randomization of the polarization, so essentially only for short paths with
no reflective multi-path or other effects. seems like more trouble than its
worth... what would you gain from it anyway?

nope, us programmers are perfectly happy, you on the other hand should
completely distrust any computer program modelling antennas out there...
NONE of them include the weak force, therefore they should not be trusted to
model your magical equilibrium antennas. you must go off and find a
different way to calculate your antenna patterns that does include the weak
force.

Thank you very much for the addition supplied. I never really
understood why hams could not accept this
From my point oif view the beauty of the Foulcalt or eddy current is
without this "pealing" on the chemical adhesion effect
that a particle has on a diamagnetic surface the ejected particle
would be without spin, and as such would not be able to have straight
line
projection within a gravitational field, a necessity for radiation.
Any book on wave guides will picture this eddy current on the inside
walls
and any book on non destructive testing will also corroberate its
presence
and yet it is still rejected by this group. When Maxwell inserted the
required units to achieve equilibrium per Newton it was the

mathematics that forcast
the presence of a levitation force that would not be identified for
several decades but stil ignored because of the dominance of wave
theory.
Cheers

No Siree, it has been several years that the idea of Neutrinos without
mass was squashed.
Two years ago it was again confirmed in experiments in Batavia,
Illinois. And ofcourse it gives CERN
its impetus for their current experiments in Switzerland
Pull yourself together David As for publishing academics require a
reference lists of quotes from other members of academia
and are loath to challenge prior papers and academics. Thus to be
published you must stay on the same track as others
with no going back for solid review. History shows that papers
supplied by non members of academia will never be accepted in their
life time.
That is why I say papers should be open source and open to challenge
from those outside academia.

>from those outside academia.

go challenge anything you want... it sounds like you don't want or need to reference any current papers since your theory goes against everything that is accepted, so just publish away. you have a web site, put something on there that is testable and see if anyone can prove it. or better yet, apply for another patent with something useful and see if anyone buys it. your magical levitating weak force neutrinos make for a good laugh now and then, but are otherwise total fantasy until you can show the equations... and not a single reputable publication will accept a paper from you without those equations.

Not just hams, Art.

Skin depth applies to a-c energy flowing along a conductor. The same principles of physics apply no matter to which end of a conductor that a-c is applied.

That is, the a-c energy reflected from the unterminated end of a conductor will travel on its outside for the same reason it traveled on the outside of that conductor when first applied to it, at its other end. Fractional wavelength conductors and your "equilibrium" are irrelevant to this.

The center conductor of rigid coaxial transmission line used in the broadcast industry is hollow, because it can carry the same amount of a-c energy as it could if it was solid (and costs/weighs a lot less).

[snip]

I agree. My statement was not quite precise.

I should have stated something like, "it is commonly understood that
polarization of waves may be categorized as being either linear or
elliptical, and
in the elliptical category the special case of circular polarization occurs
whenever
the major and minor axes of the elliptical polarization are equal."

[snip]
> Of course linear polarization can have any orientation, not just vertical
> or horizontal. And even those terms lose meaning when away from the Earth.
> However, it's often convenient to mathematically separate waves into two
> superposed components of horizontal and vertical polarization.
[snip]

Agreed!

[snip]
> The polarization of the dipole signal will be purely horizontal only
> directly broadside. The signal off the ends are purely vertically
> polarized, and in other directions neither horizontal nor vertical.
[snip]

Agreed! It is relatively difficult, and perhaps even impossible to arrange
the physical configuration of an antenna such that it emits (or receives)

wave of purely one category of polarization.

In practice though many antennas concentrate a major part of their emissions
in one polariztion form.

[snip]
> By "mixed" polarization, I assume you mean a single polarization which is
> neither horizontal nor vertical and can be described as a "mixture" of a
> purely horizontal and a purely vertical wave.
[snip]

No. What I meant by "mixed" was that, just as with daylight for example,
the field contains many polarization orientations. In fact usually outside
in daylight most of the light we see with our eyes contains very nearly
an equal distribution of all polariztions. An exception in the sky's light
is perpedicular to the suns rays where because of upper atmospheric
conditions light becomes slightly polarized. It is claimed that some people
can actually "see" this polarized light differently than normal light.
(Haider's
Brush) Of course many people know that reflected light, for example
from the surface of a lake, becomes highly polarized. This is the
reason that "Polaroid" sunglasses are used by sportsmen and others
to reduce perceived glare from reflective surfaces.

That said, mixed polarization, is also largely the case of HF waves
received over ionospheric paths. In other words HF waves received
over long distances will contain a wide distribution of linear
and perhaps circular polarizations. Thus rendering the use of single
polarized antennas relatively useless at HF by amateurs. Unless of
course one is prepared to pay the significant price in space and
equipment to implement a polarization diversity receiving system.

[snip]
> It's also difficult to get the polarizations of the antennas exactly
> right.
[snip]

Agreed!

[snip]
> There's no advantage at HF of having the antenna orientations the same if
> the path is via the ionosphere.
[snip]

True for a single antenna and receiver, which is the usual case for a ham,
see my remarks above.

However if one is willing to pay the price for several antennas and
synchronous
receiving systems then receiving gains can often be obtained by the
exploitation
of polarization diversity.

[snip]
> Interesting. Can you work an example for us? I'm curious as to what you
> use for theta in the "law's" equation.
[snip]

Theta is just the relative orientation of the polarization of the
transmitting
and receiving antennas, or in the case of an optical polarimeter, the
relative orientations of the polarizing and analyzing polarizer.

Theta is commonly illustrated in undergraduate optical laboratories and
science
experiment kits, using a couple of pieces of "Polaroid" film with the
polarization
angle marked on the film by a notch or other marking. When the
two films are aligned with their polariztion direction perpendicular there
is no
light propagation, i.e. theta is 90 degrees, and when they are aligned with
theta
equal to zero then light is propagated.

In the case of dipole antennas, theta is zero when two antennas are
co-linear and theta is 90 degrees when the antennas are perpendicular.

[snip]
> Only if it strikes the surface directly head-on. Otherwise you get an
> elliptically polarized wave. The axial ratio depends on the angle of
> incidence and, if the reflector isn't perfectly conducting, on the
> impedance of the surface.
[snip]

Agreed!

A very intersting optical phenomena to observe is to look at a mirror
through
an optical circular polarizer (polarizer in tandem with a 1/4 wave retarder)
which
renders the "image" of the circular polarizer to be black. i.e. the optical
circular polarizer eliminates the reflection. This technique is widely used
to eliminate reflections from information displays that must operate in high
sunlight with good sunlight readability. High quality high transmissivity
optical circular polarizers are relatively expensive, and so one does not
find such technology applied to consumer displays like computer
monitors, TV sets or IPhones, however optical circular polarizers are
widely used by the military for eliminating sunlight reflections from their
(expensive) information displays.

[snip]

Definition! Gosh where is Cecil when you need him? The only
problem with definitions is that there are so many of them!

"When I use a word, Humpty Dumpty said in a rather scornful tone,

"It means just what I chose it to mean - neither more nor less."

"The question is," said Alice, "whether you can make words mean so many
different things."

"The question is," said Humpty Dumpty, "which is to be Master - that's all."

> zero each cycle.
[snip]

Here there is a bit of fuzziness...

I agree that the E field of a wave is always changing at the RF carrier frequency
since it is an AC waveform. Alternating current is always changing! And so a
1 GHz carrier will always have an E field that oscillates back and forth at the
carrier (center?) frequency when analyzed by a (linear) polarimeter.

I disagree with you that a circular polarized wave has a constant E field.

Even in the case of a purely circularly polarized the E field still oscillates
at the carrier (center?) frequency when analyzed by a linear polarizer.

i.e. if a purely CP wave is received on a linear polarized antenna the
detected E field (Volts per meter) will be observed to be oscillating
at the carrier frequency. However if received on a purely CP responding
antenna this oscillating E fileld will appear to be constant.

The E field vector can be considered to be similar to the image of a
spoke on a rolling wheel. The radius of the spoke is constant, but
it's projection on the ground over which the wheel is rolling will
always be oscillating in length.

[snip]
> Circularly polarized waves have many characteristics and particular
> relationships to linearly polarized waves. The waves you're producing
> don't have some of these characteristics, like the constant amplitude.
> Your method doesn't produce circularly polarized waves even though the
> polarization does indeed change with time.
[snip]

I beg to disagree. The waves that I am describing are exactly the same.

Consider if the mechanical motor that spins my linear antenna spins at
exactly the carrier frequency. There would be then no way to tell the
difference between the two.

[snip]
> Because a circularly polarized antenna responds equally well to all
> orientations of linear polarization, the normal helix wouldn't be aware of
> the polarization rotation -- unless the polarization rotation was fast
> enough to be nearly synchronous.
[snip]

Heh, heh... what would you consider to be "fast enough"?

Would the rate of spin have to be 99-44/100 percent of the synchronous
frequency? Or would it have to be closer than that?

At what magic spin frequency would the two be indistinguisable.

FWIW... I can propose a scheme that will electronically rotate the linear
antenna
at any desired frequency, at least up to the accuracy of modern atomic clock
standards.

[snip]
> Sorry, I didn't find it "mind-blowing".
[snip]

Roy, I don't belive you have thought about it hard enough yet, for clearly
this idea
has already "blown" your mind!

For did you not state above that a circular carrier wave has a constant
amplitude?

A radio wave with constant aplitude, indeed! Something must be blown!

At zero frequency, how would a constant wave propagate?

This assumption/view that zero frequency wave can propagate is akin to
Cecil's
view that there are no reflections at DC.

I don't mean to be facitious and I am quite serious about all of this.

Just because no one has ever considered non-synchronous circular polariztion
before
does not mean that it doesn't exist, or that it may not be useful.

Me? I have already thought of several potential uses for non-synchronous
circular
polarization. How about polariztion frequency modulation? Or... how about
polariztion phase modulation? Or...

Got you thinking yet?

Thanks again for your clearly interesting comments and feedback.

More thoughts, comments?

It was stated above that the purely horizontal polarisation will occur
when the dipole is broadside
This is not correct
Using an optimiser and inserting a one liner where all dimensions are
different allows for the design to conform to Maxwell
laws in their entirety, which means the inclusion of the "weak" force
required for equilibrium

leave it up to art to take a perfectly good premise and insert utter idiocy
into it. next he'll be saying that since the magical levitating weak force
neutrinos are jumping off the antenna at an angle to the element that the
polarization is caused by them. how about it art, can you make your
levitating neutrinos rotate in different directions with left or right hand
circular antennas??

You can have diversity with respect to all polarizations except
circular
where you only have the choice of one. If you believe that antenna
programs
are utter idiocy then that will be inline with your general attitude.
I am sure that some have taken up my suggestion to check for
themselves
instead of resorting to knee jerk reactions with out foundation.
One more fool like you on this newsgroup changes little

on the contrary, i believe antenna programs and understand how they work, at one time i wrote one of my own that did well on designing phased vertical arrays... and not a single reference to the weak force in it at all! nor will you find any of the existing antenna modeling programs that use the weak force. which kind of contradicts your whole rant, you say you believe in the modeling programs and that they give results that agree with your corrupted weak force model, and yet they don't use the weak force at all... never have, and never will. nor can you state where the weak force is included in Maxwell's equations, which of course all the modeling programs are based on. so that just leaves you hanging by your magical equilibrium levitating diamagnetic neutrinos... which you still haven't explained how they work with my ferromagnetic radiators.

5226. Towers - lattice vs. tubular?

I'm starting to look for a 55' freestanding tower with house wall bracket. Am undecided on a lattice type or tubular. Being an old geezer I am not interested in the standard lattice type which requires climbing, but a nestable type to be raised and lowered by a crank or motor. I figure if it can be lowered I could work on it from the roof of my one story house. Main antenna would be a Cushcraft A4S 4-element or equivalent - wind area abt 4 sq ft. Not sure I could handle the huge X7 Big Thunder and its 7.9 sq ft., although that would be ideal.

Any first hand experience or recommendations?

This isn't a classroom problem. It is a research study that I am
conducting.

For the first case, I used a distance of 500 metres, which
corresponded to what happens to be the maximum allowed power of 1 mW.
Hence, I stated that I may be having a range issue because I was
testing the maximum distance case. That is why I provided a case for
300 metres as well.

If I'm doing something incorrectly, this is why I posted this question to the board. Stating that my math may just be wrong, doesn't really help the situation.

I will check into the Zigbee forums thank you.

About all that I can recommend is nt to do it like a local ham. His tower is next to his house, but he can not put an antenna on it from the roof and has to rent a bucket truck or a one man lift to get to the antenna. Seems he put it at the side of the house and the angle of the roof is too much to get the antenna boom from the roof to the tower. He only had a 3 element triband bean and tehn replaced it with the Stepper 3 element and still has the same problem. He does have a tower that can be lowered, but it does not do him much good for that reason.

On Sat, 06 Dec 2008 18:46:16 GMT, "Dave" <noone@nowhere.com> wrote the
lamentations of a weak mind struggling with the high concepts of an
infinitely Byzantine theory from the laboratories of ï¿½rthur:

>on the contrary, i believe antenna programs and understand how they work, at
>one time i wrote one of my own that did well on designing phased vertical
>arrays... and not a single reference to the weak force in it at all!

It is singularly impossible for them to have not included the weak
force - whose total contribution to the resulting -um- results
registers in the 13th digit to the right of the decimal point.
Dismissing this immense revelation is like arguing that a drowning man
is immune from the effects of a drunk pissing into the ocean.

>nor
>will you find any of the existing antenna modeling programs that use the
>weak force.

op. cit.

>which kind of contradicts your whole rant,

That well may be seeing that ï¿½rthur practices a self reinforcing
argument that exhibits that quality of ï¿½quilibrium: damned if you do,
and damned if you do it again.

>you say you believe
>in the modeling programs and that they give results that agree with your
>corrupted weak force model,

A corrupted weak force, the wï¿½k force?

>and yet they don't use the weak force at all...

Of course they do (op. cit.)

>never have, and never will.

Always has and always will (I already said that didn't I? (which is
what op. cit. mï¿½ns in Lat.))

>nor can you state where the weak force is
>included in Maxwell's equations,

ï¿½rthur, while rooting in the library stacks of an ancient university
located on the banks of a great (but not grand) lake, he discovered
them in the margins (long neglected as flyspecks on the page due to
their singular characteristic out 13 places to the right). Patents
are pï¿½nding, so watch your step.

As we are taxpayers, supporting inventors on the dole, it should be
our full right to be able to examine these hidden documents, but
ï¿½rthur continues to suppress their access.

>which of course all the modeling programs
>are based on. so that just leaves you hanging by your magical equilibrium
>levitating diamagnetic neutrinos... which you still haven't explained how
>they work with my ferromagnetic radiators.

The only thing he hasn't explained is the beneficial prosperities of
the color of the color-coded wire. Just as all resistors look the
same except for the colors - and we are all perfectly aware that not
all resistors are the same - hence it is a color thing. (Lest we
diverge into the side topic of wï¿½k resistance, aka Unpedance.)

Building a small 2.4 GHz detector:

<http://www.atvinderby.co.uk/2.4Ghz_SWR_Meter.htm>

Regarding the dimensions of the wire loops:

ant: 28 mm square
reflector: 30 mm square
separation: 10mm
wire: 14ga solid (1.6mm dia)

Are these dimensions center-to-center of the conductors? Or are these dimensions the space between the conductors? With a conductor diam of 1.6mm, this is more than 10 percent of one dimension (separation), so I think it's important to get it right.

Also, is the reflector to be grounded or floating?

Thanks.

Thanks for the info. I notice that the tubular and lattice towers nest
at 22' & 21'. My roof hgt is abt 16' at the peak on the ends, but only
12' on long side - where I want the tower. Might have to rethink my
placement. Or use a bucket truck, or tilt the tower on the base hinge
when mounting antenna.

>important to get it right.

It's probably not actually all that important. Quads are not highly
in their dimensioning. Altering the positioning between the driven
(active) element, and the reflector, will change the antenna's pattern
(gain and front-to-back radio) slightly, and will alter the feedpoint
impedance slightly. Neither of these changes is going to be
particularly significant (and quite possibly not easy to detect) in
this situation. The fact that there's a lot of additional metal in
the neighborhood of the antenna (the BNC connector, etc.) is probably
going to alter the pattern more than the spacing different will
(compared to a theoretically perfect quad in free space).

The pattern of a two-element quad is fairly broad, and the
front-to-back ratio isn't terribly high. It's not the best design for
pinpoint aiming / location of a microwave source... but that isn't
really what this device was intended for. As a field-strength meter,
it'll work fine (and probably just about equally well) with a 10mm
separation edge-to-edge or center-to-center.

>Also, is the reflector to be grounded or floating?

In a quad, it is usual for all of the elements other than the driven
one to be floating. Since the article says that the reflector is
fastened with a dollop of glue, I think it's safe to assume that it's
intended to be floating.

That detector is a slick little design - thanks for posting the link!

5235. NEC output in circular components...

Newsgroup: rec.radio.amateur.antenna
Date: 2008-12-06 21:53:28 UTC
From: "Peter O. Brackett" <none@no-such-domain.nul>
Message-ID: <CoGdnX_SLqTDaafUnZ2dnUVZ_hednZ2d@earthlink.com>
Source record: 19409

Group:

The celebrated Numerical Electromagnetic Code (NEC) developed largely at US taxpayer expense (Let's all Salute the US Taxpayers!) and generally released to the public for free provides algorithms for numerically integrating Maxwell's celebrated partial differential equations and so enables one to obtain numerical solutions to real practical problems such as the antenna field strengths at points in space due to modelled practical transmitting antennas.

NEC codes are available for downloading from public WWW sites. The raw NEC codes however do not have modern GUI based interfaces are required to be 'driven' by Fortran style card decks and profide outputs as files and not in graphical form.

Several enterprising folks/companies have added GUE capability including data visualization to enable a more user friendly interaction with the NEC codes.

For example Roy Lewallen's (W7EL) famous EZNEC programs are one example of the widespread use of the public NEC codes that have been 'enhanced' by Roy to provide user friendly graphical (GUI) based input/output (I/O).

Apparently the outputs from the 'raw' NEC codes provide field strengths only in rectangular co-ordinates and so... one cannot directly obtain readouts of the circular components for circularly polarized antennas.

Thus it is relatively difficult for non-experts to print out or to plot field strengths in terms of right hand or left hand circular propagation co-ordinates. For example if one attempts to model a circularly polarized antenna such as an axial mode helix, NEC (EZNEC) certainly allows the modelling to occur by breaking the helix into small segments that approximate a real helix to whatever degree of accuracy is required. The difficulty comes when one attempts to plot or graph the circularily polarized fields resulting from the modelled antenna. NEC only provides rectangular (x-y-z) components for the fields and not direct circular components for the fields.

It is relatively simple to calculate the circular components from NEC's rectangular component outputs, and a simple arithmetic transformation routine can be written to quickly and easily process the NEC outputs into circular outputs so that one can then obtain solutions for circularily polarized antennas expressed in terms of right and left hand circularly polarized components.

It seems however that none of the extant GUI equipped NEC based programs such as EZNEC have implemented this (simple) transformation.

I suppose that since the use of circularly polarized antennas is only a very small fraction of the use of rectilinearly polarized antennas and so the authors of NEC must have felt that their would not be much call for those outputs. In fact the output transform from rectilinear to circular components is trivial compared to most other aspects of NEC codes! But in truth there is not much (commercial) call or market for the use of circularly polarized output plots.

Question for our own Roy Lewallen W7EL... Roy do you think that there would be much of a market for EXNEC to provide circular polarization outputs from EZNEC, and do you have any plans to implement output plots from EZNEC in terms of circular polarization?

I can supply you with references to the needed transformations. Just a few lines of Fortran or Visual Basic should do it...

Just asking? [smile]

Hmmmm you guys are just to sceptical of poor Art's "different" biases.

The one eyed man in the land of the blind, indeed.

Have ya'll considered that Art may not be fully occupying our own four-space and may in fact be operating in several of modern string theory's higher dimensions.

After all, modern we now know as explained by John Moffat [1], that from the view of modern Physicists unfettered by actual observation and experiment that there may be at least 11 of those dimensions available to someone of Art's calibre and that perhaps... just perhaps, we "flatladers" may not even be able to comprehend Art's machinations from our own puny four space viewpoint.

All that said... we've got to get around to viewing emag fields from the viewpoint of circular components. The universe may well be better understood when viewed by circular polarization rather than by rectilinear polarization. No?

The NEC output file lists axial ratio and tilt. Nittany's NecWin Pro, and GNEC plot these results.

There is only one E field associated with a wave and, if linearly polarized, it has only one orientation or polarization. It's not like incoherent light, but akin to a laser. There is no "mixture" of polarizations in an EM wave.

Actually, you don't want synchronous receivers, or else you get a single
effective polarization just as though the antennas were combined into a
phased array. For spacial or polarization diversity, you need
intentionally non-coherent receivers.

So in your equation, what are theta for RHP and LHP, since you've said
that the equation applies to circular polarization?

That's a great attitude for a politician, philosopher, or biblical
scholar. But engineers and scientists depend on universally understood
technical terms in order to communicate. I'm free to say that my car
gets a gas mileage of 30 miles/hour and weighs 420 miles. But it
wouldn't be a smart thing to do if I intend to convey information.

When you receive a circularly polarized wave on a linearly polarized antenna, you're seeing only the component of the wave that's linearly polarized in the orientation of the antenna. This is exactly the same process as filtering a complex waveform. You've removed part of the field and are observing what's left after the filtering process, then drawing conclusions about the original waveform based on those observations, much like listening to a concert orchestra through a long pipe and deciding that orchestral sound is very ringy and limited in tonal range. It would benefit you to gain a bit of education about circularly polarized waves. You'll find that a circularly polarized wave can be created from (or broken into) two linearly polarized waves oriented at right angles and in phase quadrature. So each of the components has a time-varying amplitude, but the sum, which is the circularly polarized wave, has a constant amplitude but time-varying orientation. Your linear antenna filters out one of the components, leaving you to observe only the other.

> difference between the two.

That's right, in that case you would be producing circularly polarized waves. But only with a synchronous spin speed. As soon as you separate the rotational speed from the wave's oscillation, you have something else with different characteristics, e.g., a time varying amplitude.

> linear antenna
> at any desired frequency, at least up to the accuracy of modern atomic
> clock standards.

What you'll end up with is amplitude modulation with the modulating frequency being the beat note between your spinning speed and the wave frequency. This creates sidebands. You'll see this when the sidebands are within the bandwidth of the helix. Outside that, the helix will filter off the sidebands and you'll just see the "carrier" -- the original wave with no modulation.

> amplitude?

Yes, I did. Circularly polarized, that is.

> A radio wave with constant aplitude, indeed! Something must be blown!
>
> At zero frequency, how would a constant wave propagate?

Here's a really neat little trick you might want to add to your bag -- superposition. As I mentioned, you can create a circularly polarized wave from two linearly polarized waves. The linearly polarized waves are of course normally time-varying. As long as the propagation medium is linear (such as air), superposition says you can split the circularly polarized wave apart into two linearly polarized waves, study and

analyze how they propagate, then add the two components back together
again after the propagation. This is, incidentally, a very simple way to
see what happens when a circularly polarized wave reflects from a
surface -- analyze the linear components separately and add the results.

> This assumption/view that zero frequency wave can propagate is akin to
> Cecil's

>
> -- Pete K1PO
> -- Indialantic By-the-Sea, FL

That's about all I can do at this end. I can't make you actually pick up
a text and learn about circularly polarized waves, and until you do,
you'll have some fundamental misconceptions about them.

Guess I'm one of those folks who someone described recently as "having
the common sense educated out of me". It's served me well, since it's
enabled me able to spend a career designing a wide variety of state of
the art electronic circuits and antennas, successfully mass produced,
which work as designed. But I know it's not for everyone.

Plots and tabular output of circular polarization components has been a feature of EZNEC+ and EZNEC Pro programs since the introduction of v. 4.0 in May 2004. (The current version is 5.0.) This feature isn't included in the demo or standard programs. I see it's not properly indexed in the manual -- I've made a note to correct that at the next revision. It's described in Getting Started/What Was New in v. 4.0.

Hi Pete

I thought the FF Tab data in EZNEC was very informative for analyzing the circularity of the antennas i tried to analyze with EZNEC. Perhaps you know of some additional data that would assist me in better understanding the polarization of these antennas. Tell me what is left out of Roy's data in EZNEC.

> they work with my ferromagnetic radiators.

I explained ferro magnetism and antennas a long time ago where the
weak force becomes swamped
You should be able to come to your own conclusions when evatuating
the effect on the Tank Circuit
With respect to the weak force action it was that addition to Maxwells
laws that provided equilibrium.
Kraus gave an example of it when he empirically created pitch angle
with respect to other parameters
without a full understanding of what created it. In this Universe
there is no such thing as a straight line tho a helicoptor can
simulate it with two rotors at right angles to create equilibrium the
same as a gyroscope or a Sedgeman.
The Universe is contained within an arbitrary border in equilibrium,
you can't get away from that.
The pitch angle that Kraus uses is a creation of the weak force which
thus forbids parallelism

in antenna arrays. If your antenna that you are bragging about
contains parallelism between elements and or the ground surface
then you are NOT obtaining maximum radiation but in fact you are
increasing your losses. You really have a long way to go with respect
to antennas
and the answers you search for are not to be found in Snakesphere that
is muddied to prevent understanding.
As far as antenna programs not using the weak force, that is stupid as
it is what is termed as the "displacement" current a guess arrived at
based on the units required
But rarely do hams use computer programs as initially designed around
Maxwell but instead use a modification of such in following Yagi and
Uda
planar design which is an aproximation. All you have to do is to
provide a one liner to a optimiser to realise you are stating a load
of crap and have reached a point where you cannot handle the truth as
it reveals exactly who and what you are. Some day a knoweledgable
person will arrive on this group and ram a computer sample down your
throat and expose you and the others as just talking heads. Most of
you are like a high school student who wondered into a post graduate
lecture room where all appeared as a torrent of babble until the time
you grew up, if you ever did.
Have a great week end

http://www.satsig.net/lnb/ebno-calculator.htm is one of many sites dealing with considerations of Energy Per Bit to Noise Density Ratio, which may help you.

The Eb/No -- or to some, Eb/N0 -- influences the bit error rate (BER). Let the Eb/No go too low and the link is not error-free. Generally, a BER of better than one error in ten-to-the-eighth bits is considered to be an error-free link.

Navy satellite data links of my acquaintance usually ran at 256 kbps and, if memory serves, needed an Eb/No around 8. The modem reported the Eb/No and that value was the first thing we looked at if the mux started taking hits.

[snip]

Oh, OK... as you likely know I am one of your customers, an EZNEC user, but my version is older. :-(

There are no circular polarization outputs available in my version.

I'll purchase a new version so that I can have that capability.

Did you add the calculations to produce the circular outputs from NEC rectilinear outputs yourself or is it/was it included in the basic NEC codes?

Keep an eye out for my order. [smile]

Thanks!

[snip]

Yes indeed, we must be talking at cross purposes, since we seem to
have no disagreement on any of the above. I don't see where we differ at
all!

[snip]
>> Would the rate of spin have to be 99-44/100 percent of the synchronous
>> frequency? Or would it have to be closer than that?
>>
>> At what magic spin frequency would the two be indistinguisable.
[snip]

I would repeat the above question in a slightly different way...

How much frequency, or for that matter phase, difference must there
be between the mechanical spin frequency and the carrier frequency
before you could tell the difference between your "conventionally defined"
circular polarization and my definition?

If my antenna was spining with an angular velocity within say,
0.000000000005% of the carrier frequency, would that do it?

Or perhaps my spin rate would have to be closer to the carrier
frequency than that?

If so, then how close does it have to be to qualify to be called
circular polarization under (your) traditional/conventional
definition?

[snip]
> What you'll end up with is amplitude modulation with the modulating

[snip]

Hmmm... Yes, I agree and that's partially correct, but some of the above paragraph is
somewhat "fuzzy" to say the least.

That helix must be a very sharp [brick wall???] filter, no?

Let's get real here, no practical implementation of any kind of physical filtering
mechanism can filter with infinitely sharp transition bands. It just doesn't happen
in nature.

[snip]
> Here's a really neat little trick you might want to add to your bag --

[snip]

Heh, heh... Superposition is not a 'trick' it is a well known principle and
Roy, I agree with all of the above!

What's your point?

Bringing up superposition is fine, but you seem to raise the concept of
superposition simply as a digression here, not as a means of disproving my
assertion that mechanically spinning a linear antenna is tantamount to
conventional circular polarization.

[snip]
> That's about all I can do at this end. I can't make you actually pick up a
> text and learn about circularly polarized waves, and until you do, you'll
> have some fundamental misconceptions about them.
[snip]

Hmmm... that was a cheap shot! Unfortunately I agree, YOU cannot
make me pick up a text.

However, I can make myself do so myself, and... it may (or may not)
interest you to know that I have done so on many occasions.

In fact I have picked up several such texts, addressing such subject matter
authored by Physicists and Engineers ranging over subjects
as diverse as radio frequency antennas and optics.

Would it impress you if I sent you a picture of my personal library
of several hundred volumes, which contains perhaps a dozen or more
textbooks on electromagnetics. Since I have been examined on these
subjects at graduate degree levels by the faculty at several duly accredited
Universities it seems that there is some evidence that I may have read and
understood at least a few paragraphs from those texts that I "picked up"!
[smile]

[snip]

> as designed. But I know it's not for everyone.
[snip]

Hmmm... I too have spent (wasted?) most of several decades designing
electronic products and equipment for international markets sold in more
than 40 countries with at total sales volume exceeding $5BB dollars.

And it seems in today's world that if you combine that Engineering
experience with $2.50 you can buy a cup of coffee at Starbucks!

Now that we have suitably set the stage, lets get back to the common
sense Engineering question at hand!

All I need is a number!

Perhaps I should regurgitate the statement of Lord Kelvin about knowledge
that dear departed Reg used to quote. You know... the one about quantifying
things, the one that says you know nothing unless you can put a number to
it!

Do I really need to do that here? Reggie dear friend, are you watching from
above?

Roy, please answer the following common sense Engineering questions, just
how close must the angular velocity of my spinning antenna be to the carrier
frequency before YOU will allow it to be called circular polarization?

A simple numerical value in percentage form would do fine!

[smile]

They're calculated from the linearly polarized NEC fields Ephi and Etheta. As you said, NEC doesn't directly report LHP and RHP components but the calculation is trivial from the reported linearly polarized fields.

You have v. 3.0. If you don't have either of the upgrade notice I sent, drop me an email and I'll send you the Customer ID you need to get your upgrade discount price. You'll need EZNEC+ if you want the circular polarization features.

> at all!

For starters, a circularly polarized wave, as universally understood, has an E field which is constant in amplitude, rotates in synchronism with the rotational frequency of the field, and has a particular relationship to constituent linearly polarized components. The field you're generating doesn't, yet you're calling it "circularly polarized".

> [snip]
>>> Would the rate of spin have to be 99-44/100 percent of the synchronous
>>> frequency? Or would it have to be closer than that?

> before you could tell the difference between your "conventionally defined"
> circular polarization and my definition?

Any difference at all. If there's even a tiny difference, the E field will change in amplitude with time. If it's perfectly synchronous it won't. The rate at which it changes with time is the difference between the field rotation frequency and the frequency of the generated signal. If they're synchronous, the difference is zero, and no change in amplitude with time.

> If my antenna was spining with an angular velocity within say,
> 0.000000000005% of the carrier frequency, would that do it?

If by "it" you mean make the difference non-discernible, the answer is no. See above.

> Or perhaps my spin rate would have to be closer to the carrier
> frequency than that?

See above.

> If so, then how close does it have to be to qualify to be called
> circular polarization under (your) traditional/conventional
> definition?

They have to be identical. See above.

The question you posed earlier was different, involving detection of the
difference with a particular kind of antenna. Like the linear antenna
you used in another example, it filters the signal which alters its
properties. So my answer to this new question is different.

> [snip]

That's not required, although I see it's how you've interpreted my use
of "bandwidth". There is no such brick wall rejection region.

> Roy, I agree with all of the above!
>
> What's your point?

You don't believe that a wave with constant amplitude E field can
propagate. My point is that the constant E field amplitude circularly
polarized wave can be made of the sum of two time-varying waves. Each of
these waves can propagate. If you're familiar with superposition it
should be obvious that the original wave can be split into those
components, each component and its propagation can be analyzed
separately, and the results summed at the far end of the path. That's
how a CP wave having a constant amplitude can propagate.

> Bringing up superposition is fine, but you seem to raise the concept of
> superposition simply as a digression here, not as a means of disproving my
> assertion that mechanically spinning a linear antenna is tantamount to
> conventional circular polarization.

No, it was brought up to demonstrate how a wave having a constant
amplitude E field can propagate. You had used the argument that a
circularly polarized wave can't propagate because its E field has a
constant amplitude, as support for your incorrect assertion that the
amplitude of the E field of a circularly polarized varies with time. A
circularly polarized wave has a constant amplitude E field, which can be
easily demonstrated from the equations describing it. It propagates.
Your pseudo-circularly polarized wave doesn't have a constant amplitude
E field, which is only one way it differs from a circularly polarized wave.

> understood at least a few paragraphs from those texts that I "picked
> up"! [smile]

I'm impressed, but it's not apparent to me why, with those resources
available, you're having trouble finding how the amplitude of the
circularly polarized wave E field varies with time, or applying

superposition to discover how it propagates. Choose one or two of your texts which has the equations for circularly polarized waves. Chances are good that I have the same text, and if you'd like I can show you how to derive the instantaneous E field amplitude from the equations. But I'm afraid you would have to pick it up to find the equations.

But if you can do that, you might be able to write the equations describing your signal, and then the differences between it and the CP equations should become obvious.

Thanks for your comments and evaluation of the project. They are helpful to someone not skilled in the black art of wireless :-)

I plan to modify the design a bit, eliminating all coax connectors & adapters, using just 2 banana plugs (and supporting plastic block) as the connection to the meter.

Is it any more efficient to use copper foil or PCB material as the reflector rather than wire?

Thanks.

A novel bit of kit, looking at the photos it appears to be being used
with a DVM, depending on how you want to use it you may find an analogue
meter easier. It will show changes better than a DVM. How about buying
a movement and a box and building a totally dedicated unit? I'm tempted
to make something similar.

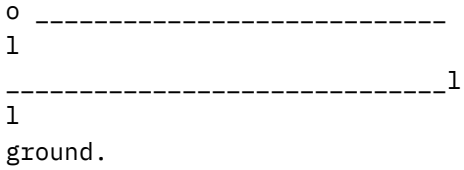
Source record: 19430

Experience anyone with this one ? Imagine a vertical half folded dipole.
One side is grounded. Like this:



o = input

Drawn laying down but of course it stands upwards. All is a 1/4 lambda long.
But now the trick: a coaxial cable can be shorted at the end too. But the lenghts needs only be 0.66 times ! So 40 metres high becomes only 26 metres.
Don't bother the shielding, that is no obstacle for magnetic fields.

I think Sal has answered this well enough. Suffice to say that if you start with the noise floor or amount of noise energy in the bandwidth you are going to use, you have to have a "margin" above that for the radio system to be able to transfer information. This even applies to morse code and voice transmission and thus the human brain's ability to do the filtering and demod! Morse code for example can actually be heard below the noise floor (or if you like a negative margin) because you can concentrate on the 500Hz odd tone rather than the wide band noise. Repeating the message that is sent also lowers the margin as it is a kind of forward error correction that might give you a few extra dB. Even a voice you know vs one you dont know lowers the margin. A trained brain is remarkably good and has a huge dynamic range as well.

Even something like a human shout of warning has "greater range" because it is a very narrow bandwith data stream. ie the message sent is binary (yes vs no) or very short (like "help" "fire" "911" or "000") rather than something like "There is a fire down here in the trees"

The margin required is more or less linked to the specification of the overall modulation method. I quoted QAM64. When you add FEC to QAM64 the margin becomes less at the expense of less data bandwidth (as more bits are sent) I saw an FEC calc for an amateur radio satellite telemetry of 6-7dB. I browsed sround and found 802.11a is around 12dB for a BER of 1 in 10E6. Data stuff tends to be layered. ie they have a basic radio modulation method (eg QAM, QPSK etc) and the FEC on top of that (eg Reed Solomon & Verterbi encoding) Above that you may also have resends at a higher layer. If you are running TCP/IP for example, TCP ensures that a packet is received and reassembled within a certain timeout period. If not it request the data again.

Hope this helps. apologies for the excessive analogies..

Cheers Bob W5/VK2YQA

An interesting design...

Keep in mind that you are building a relative, not absolute measurement device. ie you can calibrate (or not) it anyway you like. Any piece of wire will have a voltage induced into it by a passing EM field!

The only real concern is that you may want to ensure that the directivity of the quad is reasonably unidirectional. Some quad designs have pretty bad front to back performance. This may give you erronous results if you start seeing reflections or other TX's of the back of your antenna. The easy way to overcome this is to calibrate the pattern by rotating the unit in an active 2.4GHz field and noting some values. You can then use these in later tests.

Cheers Bob

Can't see much point. Makes more sense to just run a 1/4 wave to me.
Sure, the coax has a slower velocity factor than wire, but that's not
going to make a 26m antenna show the same performance as a
wire 1/4 wave. It will still be a "short" vertical vs the monopole.
I'm not sure how the current distribution would be effected.
Would need to model it.. But I'm too lazy to mess with it at the
moment. :/
BTW, there will be some extra loss in the mix using the coax vs
plain wire if you are feeding the center conductor. Much the same as
you would see using a coax dipole such as the common "bazooka".
Also, there is no advantage to using a folded vertical vs a monopole
if avoiding ground losses are the intent.
That used to be a fairly common belief that has been pretty much shot
out of the water in the last several years.
So... Where's the beef?

The antenna as drawn is a common folded monopole
configuration for VHF antennas.

What you are proposing using coax would simply be a shorted
1/4WL stub with very little common-mode current and therefore
very little radiation. Virtually all of the current would be
contained on the inside of the coax and the feedpoint impedance
of the shorted 1/4WL stub would be extremely high. If one could
succeed in shoving some current into that sky-high impedance, the
major losses would be I^2*R and dielectric with very little
energy "lost" from the system as radiation - bad idea.

Andy writes:

It sounds to me like you are describing the technique for generating
an aircraft VOR signal, which has been in use for well over 50 years.

The VOR band is 108 - 117 Mhz, and the antenna is a cardoid
pattern
that is rotated mechanically at a 30 hz rate. At a distant point
this
results in a 30 hz amplitude modulation of the received signal, which
is one of the components used in the signal processing for the
receiver to determine the direction to or from the ground VOR station.

Simply rotating the antenna does not result in circular
polarization, but
rather it changes the field strength of the radiated signal at a point
in
space.... The received signal is therefore modulated in amplitude as
the pattern passes a singular distant point in space.....

I just wanted to throw this in the mix, since rotating the antenna
has
been around for a long time.

Of course it can be done electronically now, but the initial
systems
were simply turned by a motor.

Often helpful to just tilt it back with the antenna pointing up so that it
will almost rest on the reflector element. This way you can still reach the
driven element and do tuning and testing and feed point assembly. One of
the tower manufacturers makes an MA40 tubular (40') with crank up and tilt
over come-along arrangement and was very manageable from the ground. I.m
sure 55' is available.

That should certainly work!

>Is it any more efficient to use copper foil or PCB material as the reflector
>rather than wire?

I believe not.

PCB material will probably be less efficient - standard FR-4
fiberglass-and-epoxy has significant losses at 2.4 GHz. Also, the
presence of the FR-4 will change the effective length/diameter of the
reflector loop... you might have to change the loop diameter to
compensate.

Foil would probably be bit less efficient than wire, assuming that the
width of the foil was the same as the diameter of the wire - less
surface area for the current to flow through, and perhaps more current
crowding to the edges of the foil due to skin effect. It'd also be
significantly less rugged.

Once again, neither of these losses of efficiency is likely to be
terribly important in this application, but why run the risk?

I'd just stick with solid copper wire of a reasonable diameter/gauge,
as it'll be electrically efficient and mechanically strong and rigid,
easy to get, and inexpensive.

I would think so, at 2.4Ghz there is, no doubt, "only skin effect."
Although, I doubt you would notice a great change in efficiency, it
should be prove-able, at least on paper. The biquad uses a solid
reflector plate for good reason, wire is cheaper/easier to obtain. If
the foil side faces the element, I should doubt any rf gets past it to
the fiberglass-epoxy to be "lost" in efficiency.

My statement above applies here ... all the wire element can "see" is
reflector, with foil.

Tear apart some LNA/satellite feeds to the dish, you will not see them
using wire reflectors there; I think there is good reason.

Just my opinions drawn from my readings/study, looking at commercial
equipment and hands-on ...

One thing I do totally agree with, it WILL work well with just a wire reflector.

Halfway down this page (it's a PDF doc):

<http://www.cablesandconnectors.com/PIX/CC-040.pdf>

the TNC and BNC connectors are advertised as "dual-crimp". What does this mean? "Dual" as in center in crimp and outer shield ferrule crimp?

As opposed to what? Single-crimp? That would be connectors that use the center, solid conductor as the center pin and then crimp the shield ferrule? Or...?

Newly (did you guess?) into small coax connectors and trying to get the terminology straight...

Thanks.

I just looked over the Heights web page and am very impressed. I'm surprised an aluminum tower could handle the stress from tilt-over design. Looks like everything I'd need, and very well thought out and engineered. Might get the HD (coastal) since we had 90 mph winds from H. Ike, which crashed most antennas or towers in the area, though I am sheltered up to about 25'. After looking over my own layout think a 48' tower would be all I need, with antenna on a mast then being about 6' above tallest oak tree with clear view of horizon - have flat terrain not far from Houston, but lots of trees. Counted 40 on our 1.25 acre lot. Had heck of a time stringing 120' wire antenna.

The common BNC "crimp" connectors have you solder the center pin to the center conductor of the cable, then assemble the outer with a crimp.

It works quite well in my experience, but I have yet to do this without distorting the center insulator and having to trim it with an X-acto knife to get it to fit, and I'm sure that in a critical application (like TNC in the GHz) that I'd be creating an unpredictable impedance bump with my hacking. This is bad enough with cables that have solid dielectric; I can only imagine the pain it would be with foam. In a production environment I'd almost certainly want to spring for the necessary crimp tool to crimp the inner, if the quality were there.

(This is opposed to BNC connectors where you thread in a plug to capture the outer conductor between the outer shell and a rubber insert. It also works well, but it is bulky and the connectors cost more. And you're still asked to solder the center pin on, with all of the accompanying center insulator distortion issues).

The author says he tried that and it didn't work as well:
"I tried connecting the antenna directly to a micro amp moving
coil meter, however there was very little meter deflection from
a Wireless LAN card."

Impedance too low, perhaps?

Clifford Heath.

I believe I tried lengths of a 3% to 5% shorter length with the director, than the drive element (i.e., the one in front of the reflector), settling on a 4% shorter length ... anyway, that is common in HF parasitic arrays ... this is equiv. to a 3-element quad on HF.

I just dug it out and measured it, this is what it appears to be, alright. With a spacing between driven element and director of ~0.2 wavelength, center-to-center.

Thanks for the explanation. In your previous post you suggested that I
have to "add" the margin to the path loss. My current result doesn't
make sense because the power required to transmit at 250 kpbs for
Zigbee is less than the power required to reach the receiver at a
modest 300m away. Wouldn't adding to my path loss further deteriorate
my result? I'm trying to wrap my head around this.

Andy:

Hey, thanks for your input.

I know about VOR systems and other similar systems such as TACAN. Indeed
they do use rotating antennas.

However VOR and TACAN use rotating antennas in the same way as rotating PPI
radar antennas, that is they emit linearly polarized
waves whilst rotating the direction of highest directivity/gain.

They do not emit circular polariztion as such.

Rather they emit linear polarization whilst aiming or directing the 'beam'
of linear polarized waves as they rotate.

Sort of like rotating a flashlight, or the beam of a searchlight or coastal
lighthouse.

I'm not sure that anyone yet (that includes Roy Lewalen) has fully
understood exactly what I was trying to convey.

I'm afraid that the true nature of circular polarization is not well
understood by many.

Perhaps opitical scientists understand circular polarization best, if only
because most of the important 'applications' of circular polarization are in
the field of optics rather than radio.

Tim, I solder these on the N connectors all the time with no problems.
I have an old Weller soldering gun with the tip removed. I wedge the
pin between the two electodes on the gun, slide the pin over the
tinned center conductor and pull the trigger for a couple of seconds.
The pin cools almost instantly preventing deformation of the
insulation. Ive been doing this for over 20 years using the same gun.
This may take a little practice not to melt the insulation. I
remember that it wasnt to bad getting the hang of it.

Andy comments:

Exactly right !!! And a good analogy....

Consider this then:

A patch antenna, circularly polarized, mounted at the end of a
motor shaft, rotating in the opposite direction of the polarization...
.... at a speed equal to the frequency...

Does the polarization "unravel" and emit a linear, non-rotating
polarization ?

Is this the sort of principle that you were trying to convey ??

If this is the case, any discrepancy in the motor, say 1 hz out of
10 Mhz , would result in an Efield rotating at a 1 hz rate.... and
the
receiving antenna would have to be very very very long in order
to fully receive the polarized wave..... I think....

And if the motor shaft and the frequency were identical, the Efield
would be linear, stable, and non-rotating.....

This is getting beyond my personal antenna expertise, but I still find
it
interesting..... Please pardon my lack of understanding, ... if I
still
don't "get" it....

This is your first and most significant clue to the failure of
analysis, and it is very "path loss" oriented (the path loss
differences for your two scenarios should be almost infinitesimal).
The disparity in your computations are due to transcription error, or
math error. You should have now been able to put that to rest.

>Wouldn't adding to my path loss further deteriorate
>my result? I'm trying to wrap my head around this.

This is your confusion factor, and it relates to transcription error
in the abstract: you are using the wrong formulas entirely regardless
of the accuracy or correctness of arithmetic results.

The greater part of discussion has focused on Shannon-Hartley issues
which have their own application to the full mix of your original
problem.

Try unwinding the thread so that you are not trying to force a
solution out of a broken premise. None of this really sounds like
finding the missing decimal point, or the corrupted divisor is going
to solve anything.

If you think this is still path loss related, and you are showing
results in actual implementation (bread-boarded hardware, on the
bench); then you have to open up the discussion beyond the limited
math to include the conventional problems of interference and
multipath.

Source record: 19256

Something just occurred to me. I did get to thinking.

My previous answers were wrong. Peter's spinning antenna wouldn't produce a circularly polarized wave (as universally defined) even if it was synchronous with the wave frequency. As I've said, a circularly polarized wave has constant E field amplitude; Peter's wave would have a time-varying amplitude. If it were synchronous, the nulls and peaks would always occur at the same places in the rotation cycle, so they would occur at fixed angles relative to a rotational reference point. If non-synchronous, the nulls and peaks would rotate at the beat frequency.

It seems to me that the way to mechanically generate a circularly polarized wave would be to rotate a source of *static* E field, for example, a short dipole with constant applied DC voltage at the feedpoint. That should produce a circularly polarized wave with the frequency being the rotational frequency of the dipole. At any point in space, the E field would change with time, and would propagate, and it would look exactly like a circularly polarized wave broadside to the rotation plane.

If the scheme works and radiation is occurring, then power must be going into the antenna, which in turn means it's drawing current that's in phase with the applied voltage. When stopped, no current will flow, but when rotating, it does. So how does the antenna know it's rotating? How about this -- if you instantaneously move the antenna into some position, a static E field appears there, and propagates outward at the speed of light. Closer in than the leading edge of the propagating wave, the field is static. When we rotate the dipole to a new position, it moves through the field from its previous position, which induces a current in it. Hence the current. It's fundamentally a generator, with the field being in the air.

I'd be willing to bet a moderate sum that if you did apply a DC voltage to a dipole and rotated it, you'd see an alternating current with a frequency equal to the frequency of rotation, and a circularly polarized wave broadside to the antenna. I suspect that the current and the radiated field increase in amplitude with rotational speed, so you might have to get it going really fast before you can detect the effects.

Now there's some food for thought.

So the director should be 25 mm forward (toward the uwave source) of the
driven element? (3e8 / 2.4e9) x 0.2 = ~25mm

Do these numbers look right?

Thanks.

I also noticed that he cut his elements to a precision of 0.1mm. That
would be correct if the boom were an insulator or the elements were
inserted in insulating sleeves. However, since the 10mm square boom
is metal and effectively "shorts" part of each element, the actual
element length includes part of the diameter of the boom, thus adding
approximately 5mm to each element length (not including the reflector
and driven element). A VSWR sweep test would have shown the problem.

My elements are made from #14 bare copper wire. It is difficult to measure each side, individually, when constructing the antenna. Better to cut the wire to 1 wavelength, then make your bends forming it into a square. Of course, every attempt possible should be made to keep each side 1/4 of this length, exactly.

In measuring the one before me, which I constructed, this total length, about the quad, is ~12.5cm.

However, here is a calculator I referenced in my constructions:

It is a java application, you must have java on your computer. Let me know if you can't access it and I will give you the figures it spits out, 2.4ghz = 2400mhz. Just let me know what wifi channel you wish to center on (frequency.)

I have always used #8 wire as a boom on ghz yagis' (constructed a 7 element once.) Since the boom is at a current antinode (voltage node), I ignored the boom.

The boom you mention is rather LARGE, give the freqs in question.

One of my next projects is a GOOD VSWR meter for ghz ... unfortuantly, on the list of priorities here, it is low on the list ... :-(

I have just tended to take the % signal readings on the chans as good enough, and trimmed my antennas accordingly. I know, this does NOT take into account the functioning/power-fluctuations/antenna(s)/etc. of the AP over these ranges ...

But, excellent point, glad you mentioned it ... but you are right, my elements end up being filed down a bit from the figures the calculator spits out ...

Warm regards,
JS

Maybe, but more likely, not enough RF to do anything useful with an
un-amplified meter.

What's missing from everyone's posting is what they plan to do with
this field strength meter.

Let's play with the numbers. The average wi-fi access point belches
about +12dBm (32 mw) RF into an antenna with perhaps 2dBi gain. The
FSM has a gain of perhaps 0dB. At a distance of about 3 meters (10ft)
the path loss at 2.4GHz is about 50dB which will deliver about -30dBm
to the diode. On the most sensitive voltage range, the DVM has an
input impedance of at least 1Mohm and can be treated like an open
circuit load to the detector.

-30dBm into 50 ohms is 0.224 vrms. Transforming linearly from 50 ohm
reference to perhaps 150 ohms loop antenna impedance yields about
600mv rms. (Note: I know this is a bad guess but it's midnight and
I'm tired). Resonating the loop probably raises the impedance even
higher, thus resulting in even more rectified voltage.

The resultant DC voltage will be about the same at about 600mv DC.
However, for wi-fi use, the xmit duty cycle is quite low, sending just
beacons, when there is no traffic moving. The 1000pf cap will need to
be paralleled with a much larger cap in order to form a usable peak
detector.

So, with a high imput impedance DVM the antenna and detector is quite
efficient and can generate quite a bit of voltage. However, when the

DVM is replaced with a non-amplified meter, the relatively low impedance of the meter shorts out the diode and signifigantly reduces the Q of the resonant loop antenna, resulting in much lower detected voltage.

I've built several transmitter hunt "sniffers" using almost exactly the same circuit, except that I use a hot carrier Schottky diode for the RF detector, and the cheapest Harbor Freight DVM (because it always gets destroyed or lost during the hunt). For 2.4GHz, I use a dish antenna, RF amplifier, step-up xformer (coax balun), diode detector, and DVM.

I also made a really ugly hack that uses a satellite TV signal meter.
<http://www.sadoun.com/Sat/Products/Accessories/Meters/SF95L-DSS-FTA-Satellite-Signal-meter.htm>
These work from about 900 to 1800MHz with a minimum detectable meter sensitivity of about -70dBm. They are comatose at 860 (cellular) and 2.4GHz but are great for 900 and 1900MHz (PCS) sniffing. The input port is connected to a 900MHz or 1.2GHz antenna of any sorts. The output goes to a 75 ohm load and a 12V battery (gel cell) through an RF choke.

What about surplus directional couplers and a bolometer set (various
military versions used to be quite affordable)? Used to show up at
hamfests regularly too, covered 1 to 20 GHz or so in the kit; sorry
I forget the AN number at the moment, but it came with half a dozen
directional couplers for the various bands and lots of adapters.

Michael

<http://pe2er.nl/wifiswr/>

I've built several. They work nicely and are a very important tool.
My main inspiration was blowing up my Wiltron Model something SWR
bridge and discovering the exhorbitant cost of a repair or
replacement. The designs are sufficiently similar that I can
substitute. Of course, it's not flat over many decades of bandwidth,
but for fairly narrow bands, it's quite adequate.

>I have just tended to take the % signal readings on the chans as good
>enough, and trimmed my antennas accordingly. I know, this does NOT take
>into account the functioning/power-fluctuations/antenna(s)/etc. of the
>AP over these ranges ...

I have a handy distant reference signal for 2.4GHz. It's line of
sight and creates no Fresnel Zone issues, so it's useful for antenna
testing. I start with my "standard" gain panel antenna and take a
measurement. I then take the antenna under test, and compare. I
rarely make an absolute level measurement. It's always relative to
some other antenna of known characteristics.

The only problem is that I have to climb onto my roof to do the
measuring. I'm currently at the tail end of radiation oncology (no
big deal), which makes me kinda tired. I find myself somewhat tipsy
on the roof, so no antenna measurements for a few more weeks. One
might also suggest that it affects my math and memory, but they're
currently just as bad as always.

>But, excellent point, glad you mentioned it ... but you are right, my
>elements end up being filed down a bit from the figures the calculator
>spits out ...

Suggestion: I always build a 3 element yagi first. Just the
director, driven element, and reflector. With the antenna on the
bench (after clearing off the chain saw and bicycle repair debris), I
run a fairly wide sweep using a reflection coefficient bridge or VSWR
bridge to an oscilloscope. I then trim the various elements for
resonance. My sweeper has a marker generator, but an external
generator (or wi-fi trash generator) can also be used. Adding
additional elements does change the tuning a bit, but the really big

frequency determining elements are the first 3 elements.
<http://802.11junk.com/jeffl/pics/home/slides/lab.html>
Incidentally, don't forget the mounting bracket. I just hate it when
I prototype an antenna, and then find that the bracket, radome,
potting foam, serial number sticker, or other irrelevent hardware
detune the antenna.

Another trick that I use with wire rod type of antennas is to thread
the end of the rods. Attached to these are threaded standoffs. These
can be rotated to adjust the length of the elements. Also, don't
forget to round off or chamfer the ends of each element to improve the
bandwidth.

1AM. Time to give up before I start babbling nonsense.

Hmmm, max power for a wifi router is 1 watt!

Here is a full power one:

http://www.wirelessnetworkproducts.com/index.asp?PageAction=VIEWPROD&ProdID=1425

The router I presently use is "belching" 500mw into a 7.5db antenna
(well, I might question the 7.5db ...)

Throw out your access point man! Get a decent one ...

>Hmmm, max power for a wifi router is 1 watt!

I said "average wi-fi access point". 1 watt routers are relatively
rare among the common home wireless routers. Most run about 32mw.
Some Buffalo models run about 250mw. 2wire 2701 can run up to about
450mw. I think Enginius also makes one at around 1 watt.

The problem with this is what I call the "alligator" effect. An
alligator is an animal with a big mouth and small ears. Running a 1
watt access point will make the xmitter heard over a much wider area
than it can hear the responses from the clients. Unless the other end
of the link (i.e. client radios) are also running the same high power
level, the range will be limited by the clients tx power. In other
words, the system gain and power levels in both directions have to be
evenly matched to avoid turning the high power access point into what
I consider to be no better than a jamming transmitter. If you need a
slogan, you should use "only as much power as necessary" which doesn't
mean crank it up to the max. Please print this slogan on a large sign
and plaster it in front of your desk until the meaning sinks in. Also,
note that most modern communications technologies includes automatic
transmit power control (usually based on RX SNR or BER) to prevent
alligators and systems like yours from becoming a problem.

Turn down the power to about 100mw. The antenna is fine because it
results in a symmetrical improvement in system gain. Also, give

yourself a slap on the wrist, repent your evil ways, and pray for
forgiveness.

Yes, my AP's software allows for power control. Indeed, the AP will,
automatically, only supply enough power to make a, almost, error free
transmission link.

Having one side of transmission link error free is MUCH superior to have
both sides error prone!

However, although I have a pocketfull of various USB dongles, my
external USB wifi "card" is the highest output I could find which is
cost effective (@ 500mw.) External USB being powered off the USB buss
must stay 500ma (@ 5v) or below, total consumption. And, would more
than allow for a 1 watt USB dongle.

Here is a USB card to match my router:

http://www.data-alliance.net/servlet/the-90/802.11g-USB-802.11b-802.11n/Detail

Try one, you'll like it, "Mikey does!" <grin>

Hello, and that's quite correct, Roy. Having read the OP's statements and others in this thread I would like to recommend that one step back from antennas for a moment in order to examine the generation of an ellipse (representing the locus of points of a rotating E (or H) field. The parametric equations take the form x(t) = A*cos(2*pi*f*t) and y(t) = B*cos(2*pi*f*t + phi). (These equations are of the same form that generate the familiar Lissajous patterns except that for Lissajous the x and y values differ in frequeny.)

While polarization is a convenient concept in electromagnetic wave propagaion there's no reason that we couldnt just treat it as the superposition of two separate Ex (or Hx) and Ey (or Hy) waves. Of course we have to pay attention to amplitude and phase relationships.

I think investing some time with this math (it's not all that difficult) will provide one with insight into the concept of polarization and perhaps head off some misconception. If anyone is interested and has Mathcad, I've got a worksheet that allows one to vary these parameters, plots the resulting ellipse (or circle or line) and also calculates ellipticity (axial ratio) and eccentricity. All I have to know is that Circular Polarization always helps when one
end of the path is prone to random polarizations, even with the 3 dB
power loss.

A source of endless coffee-time debates where I used to work! No, the current into the rotating dipole would be DC and the means of rotation at the radio frequency would take the place of the 'transmitter'. If the current were alternating then the radiated electric field would be discontinuous but it isn't; it has constant magnitude. Between two such systems separated by many wavelengths, if there were no anisotropic material around, reciprocity would apply and a means of conveying DC by radio would be created!

However, intriguing and amusing as this analogy might be I wonder if it really has any practical value. For real mechanical rotating parts the frequency would be limited to something rather low like the tens of kHz at which Alexanderson alternators work, and then the wavelength would be so long that it would probably be impossible to construct an efficient radiator*. The quickest moving antenna I've encountered was a commutated plasma antenna, using a construction similar to a 'dekatron' tube, but even then the length of the radiator was so small that SHF would be needed to achieve worthwhile radiation efficiency* and the maximum commutation speed was limited to a few MHz by the time it takes to establish the plasma at each step in the commutation cycle.

*(Of course, the conventional principles of radiation resistance vs. loss resistance may need 'massaging' to bring them into line with the concept of creating transverse waves by rotating a dipole connected to a battery!)

Thanks for the link. The calculator works for me.

One remaining Q: how do I take into account the "pigtails" of the driven element? A nice square loop is nice, but I've got to connect it to the (relatively) big diode, and this requires a bit more wire from the loop to the diode (on the + side of the loop) and to the meter connector (on the - side). Do I include these wire lengths in the loop size calculation? Or ignore them?

Or does the 1000pF cap effectively terminate the loop (re. size)?

Thanks.

Hi Chris

I am not smart enough to analyze the effects of rotating a dipole with DC applied to it, but I have doubts that it would create a "far field". Did you guys ever figure out how the "DC dipole" generates a Far Field?

I beg to differ. Unless I missed something in my post-midnight scan
of the specs, the wireless router's TX power is set and forget. If it
receives an extremely strong signal level report in the 802.11
management packet, the power remains the same. The ability to do
power control is there (because each device reports its RX signal
strength and SNR) but very few access points even try.

>Having one side of transmission link error free is MUCH superior to have
>both sides error prone!

I beg to differ. You're creating un-necessary interference. Let's
play with the numbers.

The commodity wireless router belches about +12dBm. Yours is
allegedly +27dBm. Range doubles for every 6dB increase in TX power.
Therefore, your TX range is:
(27 - 12) / 6 = 7.5
time more than would be with a commodity wireless router. In terms of
coverage area, that's:
7.5^2 = 56.3
times the area. Assuming a uniform density of WLAN users in your
vicinity, you're trashing 56.3 times as many users or systems as
necessary.

You're also partly wrong about asymmetrical systems being superior.
The transition between a fairly good BER or PER (packet error rate) is
rather abrupt. What happens is that the AP simply slows down the data
rate until the PER improves. Since the connection speed can be
different in each direction, you'll get very good speed in one
direction, and probably very slow speed in the other. In addition,
things go insane above 54Mbits/sec connection speed. You might have
enough signal to go faster than 54Mbits/sec in one direction, but if
it's lacking in the other direction, the AP will simply revert to
802.11g and limit the speed in the stronger direction to 54Mbits/sec.
That's not a problem as few systems can operate reliably at
54Mbits/sec beyond a few meters range and in the presence of
interference.

Meanwhile, you're operating an alligator, jamming 56 times as many
users as necessary, and polluting the airwaves with your overpowered
xmitter. It's like operating a kilowatt xmitter in the middle of the
QRP frequencies. Your stuff gets through, but nobody else's. I
suggest you do the math, repent your evil ways, offer sacrifice to the
radio gods on the hibachi, slap yourself on the wrist several times
for penitence, and stop playing with the dark side.

>However, although I have a pocketfull of various USB dongles, my

>cost effective (@ 500mw.) External USB being powered off the USB buss
>must stay 500ma (@ 5v) or below, total consumption. And, would more
>than allow for a 1 watt USB dongle.

You would do better with a directional antenna, so as to not both
pickup and deliver interference from other systems. Antennas with
gain also improve the system gain in both directions, thus preventing
the creation of an alligator.

>Here is a USB card to match my router:

>
>Try one, you'll like it, "Mikey does!" <grin>

Nope. Instead, I was instrumental in convincing at least one mesh
wi-fi vendor to reduce their poletop TX power, as they were causing
most of their own interference. Asymmetric systems suck.

Hey OM
What size gun did you has a 240watt? How did you get the electrodes so
close together? Isn't the center pin of an N connector really small?
Or maybe you making lots 7/8 inch of heliax cables huh? Where the
center conductor is like 3/8 in copper tubing. Where the 3/8 inch
copper tubing would conduct all the heat away from the insulation?

Now that I think about it, you're right -- the current would have to be DC, so there would be only DC power into the dipole.

Interesting that you and your co-workers thought of and debated this. I've given it less than an hour of thought since it popped into my head, so you've had a lot more time to work out the details. Sounds like it might work something like I described, then.

I can't see where this could possibly be of any practical use. For me it was simply a mind exercise spurred by Peter's musings, resulting from wondering just how a mechanical system could be made to generate a CP wave.

Indeed. And it seems there wouldn't be any skin effect, then, with only DC going to the wire. And what about current distribution on the dipole?

You don't need to include diode lead length in the quad antenna
calculations. The "loop" in the quad driven element is just an LC
tuned circuit. It's as bit less than one wavelength around the loop
and resonated to 2.4GHz by the tuning cap. The diode and other
components do add some capacitance, which will lower the frequency
somewhat, but the adjustment cap is substantially larger than these
capacitances. For example, the off capacitance of a Schottky diode is
about 0.5pf. You do need to keep lead length short as the added
inductance will act as an RF choke.

However, instead of the giant diode, I suggest something smaller and
better, such as a Schottky diode:

Hi Roy

I have problems with believing there will be any current in either dipole.
What am I missing?

It requires energy to create a far field, since the far field is a form of energy. I explained why I thought power might be consumed by the antenna -- current would flow due to coupling with the field still present from previous positions (although I mentioned alternating current while Chris correctly pointed out that it would have to be DC). I don't see any problem with conversion of the DC into AC. It's done all the time with spinning magnets -- look at the alternator in your car for example. And in times of yore, RF was generated directly with high speed alternators. The principle is very similar to, if not exactly the same as, the scheme I described.

The whole thing is just a mental exercise to help gain a better understanding of the nature of a circularly polarized field.

Indeed, and I would add that the spinning dipole fed with a constant voltage appears the same as a stationary dipole fed with an alternating voltage with respect to any chosen linear polarisation.

I was once told of a method of measuring the radiation patterns of large installed antennas by 'flying' near to them a small metal rod rotating about an axis that passes perpendicularly through the middle of the length of the rod. By detecting, synchronously with rotation of the rod, changes in the terminal VSWR (or reflection co-efficient for voltage) the near-field radiation pattern could be assessed (i.e. an impression of the aperture current distribution) from which the far-field patterns could be derived by Fourier transform in the normal way (acknowledgement is due to the late Dick Manton). There is a range of 3D angles over which the axis can vary without upsetting the measurement. I don't know if this was ever implemented, e.g. to measure the patterns of a television transmitting antenna - a helicopter carrying a measuring receiver is used in the far field nowadays.

Hi Art, not saying that I disagree with your sentiments, but the
paradigm shifted, and we allowed it to happen.

Bell labs is a good (bad?) example of just what happened:

http://en.wikipedia.org/wiki/Bell_Labs

Is an interesting reference, you really should read it.

They sure came up with a lot of interesting innovations and inventions.

But what is telling is the last two sentences of the article:

Start quote

>> As of July 2008, however, only four scientists remained in physics basic research
>>according to a report by the scientific journal Nature.[4]
>>
>> On August 28, 2008, Alcatel-Lucent announced it was pulling out of basic science,
>> material physics, and semiconductor research, and it will instead focus on more
>> immediately marketable areas including networking, high-speed electronics,
>> wireless networks, nanotechnology and software.[5]

End quote

No doubt their next quarter profits will look good. Or did. They'll have
to find something for an encore to increase the profits next quarter.
But for companies that rely on innovation and invention, they are eating
their seed corn.

- 73 de Mike N3LI -

Hi Roy

When you write "current would flow due to coupling with the field still present from previous positions", do you submit that more power is required to rotate a dipole with no DC on it than one with DC on it?

I will respectfully submit that a car alternator doesnt so much spin a magmetic field as it Rotates the field past a conductor. A car alternator is a lumpy magnetic field that is spun past stationary coils of wire. There is no misunderstanding about inductive coupling of close by conductors. My question related to far field "radiation". I am aware that my understanding of far Field radiation is very limited, so i dont propose that i have answers. I do have question about generating a far field by spinning a DC excited dipole.

Hi Chris

Tell me, did you guys ever decide that there would be a far field
generated by the spinning dipole with DC on it? I dont refer to the
inductive field.
Maybe there is no way to separate Far Field from any condition where an
inductive field is generated.

Jerry,

I think you're right - in the far field there is spherical spreading of power without regard to separate magnetic and electric components that an antenna, of whatever form, might produce. Of course the radiated power incident on any surface can be represented by an equivalent value of electric or magnetic field strength but this is on strict understanding that the counterpart (magnetic or electric) component is present with the requisite field strength (E/H = Zo = 377 ohms in free space) and PFD = E2/Zo.

The answer to your first question is 'yes - hypothetically' there 'would be a far field generated by the spinning dipole with DC on it' but this shouldn't be taken as a recipe for some wacky rotating machine. As I outlined earlier, there is probably little practical application for this interesting analogy because if it were ever put into practice it would probably be hopelessly inefficient and transformation of Maxwell's equations into an inertial frame spinning at the radio frequency is hard, to say the least! As has been suggested, it's probably best to take the concept no

further than an interesting thought exercise - if you don't understand that, don't worry, you're not missing much

Chris

Too late! ;-) I've already made the "coat hanger" four-bay bowtie, but
with weld rod rather than hangers. ;-)

It was on youtube:
http://www.youtube.com/watch?v=EWQhlmJTMzw

Thanks!
Rich

A not-uncommon scenario, I think. I've seen APs which put out a
signal that has useful strength for blocks, and yet you have to be
within about 100 feet of them to establish contact with a typical
client system.

This same issue is significant in other bands, as well. My area's
ham-radio VHF/UHF repeater coordination group has a firm principle...
a coordinated repeater's transmit coverage and receive coverage should
be consistent. Having an ultra-high-powered transmitter simply causes
interference well outside the repeater's practical use range.

Having overly-sensitive receivers can also be a problem, albeit a
lesser one, as it means that the repeater can be "keyed up" by remote
stations too far away to hear the repeater properly. It's less of
a problem, though, as most repeaters use CTCSS tone squelch these days
and won't respond to signals intended for co-channel repeaters with a
different CTCSS tone. I don't think this is an issue for 802.11
access points at all.
